Is it not possible that we may find in this perpetual lightning, some clue to the origin of earth-currents everywhere? and in the diurnal variation in the discharge, some probable reason for the hourly variation of the aurora, and of some magnetic elements? No doubt it is at present difficult to connect the electricity of lightning with the electro-magnetic effects of terrestrial magnetism or the aurora; and though Edlung's theory is defective in this respect, I cannot help thinking that he is right in collating thunderstorms on the equator with the glow discharge of electricity on the Arctic circle; and it is in the hope that the discovery of the constancy of electrical discharge in the "doldrums" may perhaps assist in the evolution of a true theory of the aurora, that I have penned this short notice.

Scorpion Virus

PROF. BOURNE'S experiments, related in the Proceedings of the Royal Society of January 6, 1887, seem to establish the fact that although the scorpion may be provoked to strike and wound itself or another scorpion, it is incapable, in either case, of causing any toxic action, however active the virus may prove in respect of other creatures. That it is, in short, with the scorpion as it is with the cobra or viper: they poison other creatures, but not themselves or each other.

Some years ago an exhaustive series of experiments brought me to the conclusion that a cobra is not poisoned by cobra virus, whether inoculated by its own fangs, by those of another cobra, or by a hypodermic syringe. The same in the case of daboia and other viperine snakes.

It seemed, however, that the bungarus, a less deadly snake than the cobra, occasionally is affected, though slowly, by the cobra virus, but that it escapes more frequently than it suffers; and when it does suffer the effect of the poison is greatly diminished. On the other hand, non-venomous snakes, lizards, frogs, fish, mollusca, and other low forms of life, all rapidly succumb to snake poison.

The details of these experiments are to be found in the "Thanatophidia of India," published in 1872, and in referring to them Prof. Bourne remarks: "They show conclusively that the cobra poison will not affect a cobra, and will not even affect the viperine ptyas." I would correct the latter part of the quotation so far as to say that the ptyas is a colubrine harmless snake, not a viperine snake, and that it rapidly succumbs to the cobra virus.

Prof. Bourne has helped to dispel another of the popular delusions which cling round venomous creatures.

J. FAYRER

THE RELATION OF TABASHEER TO MINERAL SUBSTANCES

MR. THISELTON DYER has rendered a great service, not only to botanists, but also to physicists and mineralogists, by recalling attention to the very interesting substance known as "tabasheer" (NATURE, vol. xxxv. p. 396). As he truly states, very little fresh information has been published on the subject during recent years, a circumstance for which I can only account by the fact that botanists may justly feel some doubt as to whether it belongs to the vegetable kingdom, while mineralogists seem to have equal ground for hesitation in accepting it as a member of the mineral kingdom.

It is very interesting to hear that so able a physiologist as Prof. Cohn intends to investigate the conditions under which living plants separate this substance from their tissues. That unicellular Algæ, like the Diatomaceæ, living in a medium which may contain only one part in 10,000 by weight of dissolved silica, or even less than that amount, should be able to separate this substance to form their exquisitely ornamented frustules is one of the most striking facts in natural history, whether we regard it in its physiological or its chemical aspects.

Sir David Brewster long ago pointed out the remarkable physical characters presented by the curious product of the vegetable world known as "tabasheer," though so far as I can find out it has not in recent years received that attention from physicists which the experiments and observations of the great Scotch philosopher show it to be worthy of.

Tabasheer seems to stand in the same relation to the mineral kingdom as do ambers and pearls. It is in fact an *opal* formed under somewhat remarkable and anomalous conditions which we are able to study; and in this aspect I have for some time past been devoting a considerable amount of attention to the minute structure of the substance by making thin sections and examining them under the microscope. It may be as well, perhaps, to give a short sketch of the information upon the subject which I have up to the present time been able to obtain, and in this way to call attention to points upon which further research seems to be necessary.

From time immemorial tabasheer has enjoyed a very high reputation in Eastern countries as a drug. Its supposed medicinal virtues, like those of the fossil teeth of China and the belemnites ("thunderbolts") of this country, seem to have been suggested by the peculiarity of its mode of occurrence. A knowledge of the substance was introduced into Western Europe by the Arabian physicians, and the name by which the substance is generally known is said to be of Arabic origin. Much of the material which under the name of "tabasheer" finds its way to Syria and Turkey is said, however, to be fictitious or adulterated.

In 1788 Dr Patrick Russell, F.R.S., then resident at Vizagapatam, wrote a letter to Sir Joseph Banks in which he gave an account of all the facts which he had been able to collect with respect to this curious substance and its mode of occurrence, and his interesting letter was published in the Philosophical Transactions for 1790 (vol. lxxx. p. 273).

Tabasheer is said to be sometimes found among the ashes of bamboos that have been set on fire (by mutual friction?). Ordinarily, however, it is sought for by splitting open those bamboo stems which give a rattling sound when shaken. Such rattling sounds do not, however, afford infallible criteria as to the presence or absence of tabasheer in a bamboo, for where the quantity is small it is often found to be closely adherent to the bottom and sides of the cavity. Tabasheer is by no means found in all stems or in all joints of the same stem of the bamboos. Whether certain species produce it in greater abundance than others, and what is the influence of soil, situation, and season upon the production of the substance are questions which do not seem as yet to have been accurately investigated.

Dr. Russell found that the bamboos which produce tabasheer often contain a fluid, usually clear, transparent, and colourless or of a greenish tint, but sometimes thicker and of a white colour, and at other times darker and of the consistency of honey. Occasionally the thicker varieties were found passing into a solid state, and forming tabasheer.

Dr. Russell performed the interesting experiment of drawing off the liquid from the bamboo-stem and allowing it to stand in stoppered bottles. A "whitish, cottony sediment" was formed at the bottom with a thin film of the same kind at the top. When the whole was well shaken together and allowed to evaporate, it left a residue of a whitish-brown colour resembling the inferior kinds of tabasheer. By splitting up different joints of bamboo Dr. Russell was also able to satisfy himself of the gradual deposition within them of the solid tabasheer by the evaporation of the liquid solvent.

In 1791 Mr. James Louis Macie, F.R.S. (who afterwards took the name of Smithson), gave an account of his examination of the properties of the specimens of tabasheer sent home by Dr. Russell (Phil. Trans. vol. lxxxi., 1791, p 368). These specimens came from Vellore, Hydrabad, Masulipatam, and other localities in India. They were submitted to a number of tests which induced Mr. Macie to believe that they consisted principally of silica, but that before calcination some vegetable matter must have been present. A determination of the specific gravity of the substance by Mr. Macie gave 2·188 as the result; another determination by Mr. Cavendish gave 2·169.

In this same paper it is stated that a bamboo grown in a hot-house at Islington gave a rattling noise, and on being split open by Sir Joseph Banks yielded, not an ordinary tabasheer, but a small pebble about the size of half a pea, externally of a dark brown or black colour, and within of a reddish-brown tint. This stone is said to have been so hard as to cut glass, and to have been in parts of a crystalline structure. Its behaviour with reagents was found to be different in many respects from that of the ordinary tabasheer; and it was proved to contain silica and iron. The specimen is referred to in a letter to Berthollet published in the *Annales de Chimie* for the same year (October 1791). There may be some doubt as to whether this specimen was really of the nature of tabasheer; if such were the case, it would seem to have been a tabasheer in which a crystalline structure had begun to be set up.

In the year 1806, MM. Fourcroy and Vauquelin gave an account of a specimen of tabasheer brought from South America in 1804 by Humboldt and Bonpland (*Mém. de l'Inst.*, vol. vi. p. 382). It was procured from a species of bamboo growing on the west of Pichincha, and is described as being of a milk-white colour, in part apparently crystalline in structure, and in part semi-transparent and gelatinous. It was seen to contain traces of the vegetable structure of the plant from which it had been extracted. On ignition it became black, and emitted pungent fumes.

An analysis of this tabasheer from the Andes showed that it contained 70 per cent. of silica, and 30 per cent. of potash, lime, and water, with some organic matter. It would, perhaps, be rash to conclude from this single observation that the American bamboo produced tabasheer of different composition from that of the Old World; but the subject is evidently one worthy of careful investigation.

It was in the year 1819 that Sir David Brewster published the first account of his long and important series of observations upon the physical peculiarities of tabasheer (Phil. Trans., vol. cix., 1819, p. 283). The specimens which he first examined were obtained from India by Dr. Kennedy, by whom they were given to Brewster.

Brewster found the specimens which he examined to be perfectly *isotropic*, exercising no influence in depolarising light. When heated, however, it proved to be remarkably *phosphorescent*. The translucent varieties were found to transmit a yellowish and to reflect a bluish-white light—or, in other words, to exhibit the phenomenon of *opalescence*. When tabasheer is slightly wetted, it becomes white and opaque; but when thoroughly saturated with water, perfectly transparent.

By preparing prisms of different varieties of tabasheer, Brewster proceeded to determine its refractive index, arriving at the remarkable result that tabasheer "has a lower index of refraction than any other known solid or liquid, and that it actually holds an intermediate place between water and gaseous bodies!" This excessively low refractive power Brewster believes to afford a complete explanation of the extraordinary behaviour exhibited by tabasheer when wholly or partially saturated with fluids. A number of interesting experiments were performed by saturating the tabasheer with oils of different refractive powers, and by heating it in various ways and under different conditions, and also by introducing carbonaceous matter into the minute pores of the substance by setting fire to paper in which fragments were wrapped.

The mean of experiments undertaken by Mr. James Jardine, on behalf of Brewster, for determining the specific gravity of tabasheer, gave as a result 2·235. From these experiments Brewster concluded that the space occupied by the pores of the tabasheer is about two and a half times as great as that of the colloid silica itself!

From this time forward Brewster seems to have manifested the keenest interest in all questions connected with the origin and history of a substance possessing such singular physical properties. By the aid of Mr. Swinton, Secretary to the Government at Calcutta, he formed a large and interesting collection of all the different varieties of tabasheer from various parts of India. He also obtained specimens of the bamboo with the tabasheer *in situ*. In 1828 he published an interesting paper on "the Natural History and Properties of Tabasheer" (*Edinburgh Journal of Science*, vol. viii., 1828, p. 288), in which he discussed many of the important problems connected with the origin of the substance. From his inquiries and observations, Brewster was led to conclude that tabasheer was only produced in those joints of bamboos which are in an injured, unhealthy, or malformed condition, and that the siliceous fluid only finds its way into the hollow spaces between the joints of the stem when the membrane lining the cavities is destroyed or rent by disease.

Prof. Edward Turner, of the University of London, undertook an analysis of tabasheer, the specimens being supplied from Brewster's collection (*Edinburgh Journal of Science*, vol. viii., 1828, p. 335). His determinations of the specific gravities of different varieties were as follows:—

Chalky tabasheer	2·189
Translucent tabasheer	2·167
Transparent tabasheer	2·160

All the varieties lose air and hygroscopic water at 100° C., and a larger quantity of water and organic matter (indicated by faint smoke and an empyreumatic odour) at a red heat. The results obtained were as follows:—

	Loss at 100° C.	Loss at red heat
Chalky tabasheer	0·838 per cent.	1·277 per cent.
Translucent tabasheer	1·620 ,, ,,	3·840 ,, ,,
Transparent tabasheer	2·411 ,, ,,	4·518 ,, ,,

Dr. Turner found the ignited Indian tabasheer to consist almost entirely of pure silica with a minute quantity of lime and vegetable matter. He failed to find any trace of alkalies in it.

In 1855, Guibourt (*Journ. de Pharm.* [3], xxvii. 81, 161, 252; *Phil. Mag.* [4], x. 229) analysed a specimen of tabasheer having a specific gravity of 2·148. It gave the following result:—

Silica = 96·94
Potash and lime = 0·13
Water = 2·93
Organic matter = trace

Guibourt criticised some of the conclusions arrived at by Brewster, and sought to explain the source of the silica by studying the composition of different parts of the bamboo. While the ashes of the wood contained 0·0612 of the whole weight of the wood, the pith was found to contain 0·448 per cent., the inner wood much less, and the greatest proportion occurred in the external wood. On these determinations Guibourt founded a theory of the mode of formation of tabasheer based on the suggestion that at certain periods of its growth the bamboo needed less silica than at other times, and that when not needed, the silica was carried inwards and deposited in the interior.

In the year 1857, D. W. Rost van Tonningen, of Buitenzorg, undertook an investigation of the tabasheer of Java, which is known to the natives of that island under the name of "singkara" (*Naturkundig Tijdschrift voor Nederlandsch Indië*, vol. xiii., 1857, p. 391). The specimens examined were obtained from the *Bambusa apus* growing in the Residency of Bantam; it is described as resembling in appearance the Indian tabasheers. Its analysis gave the following result:—

Silica = 86·387
Iron oxide = 0·424
Lime = 0·214
Potash = 4·806
Organic matter = 0·507
Water = 7·632

Total ... 100·000

Apart from the question of its singular mode of origin, however, and its remarkable and anomalous physical properties, tabasheer is of much interest to mineralogists and geologists. All the varieties hitherto examined, with the exception of the peculiar one from the Andes, are in composition and physical characters true opals; this is the case with all the Indian and Java varieties. They consist essentially of silica in its colloidal form, the water, lime, potash, and organic matter being as small and variable in amount as in the mineral opals; and, as in them, these substances must be regarded merely as mechanical impurities.

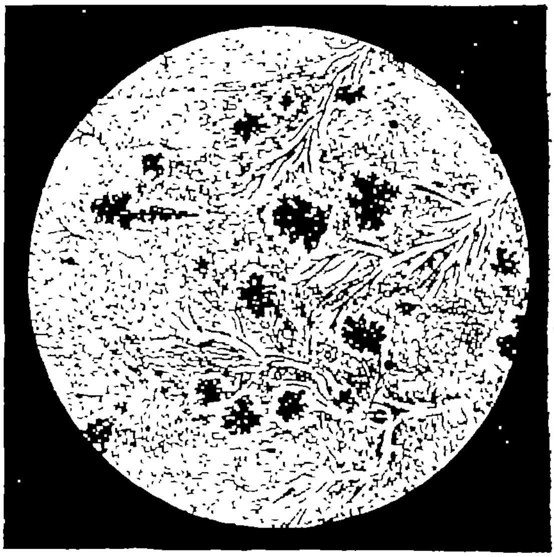
The tabasheers must be studied in their relations on the one hand with certain varieties of the natural semi-opals, hydrophanes, beekites, and floatstones, some of which they closely resemble in their physical characters, and on the other hand with specimens of artificially deposited colloid silica formed under different conditions. Prof. Church, who has so successfully studied the beekites, informs me that some of those remarkable bodies present singular points of analogy with tabasheer.

By the study of thin sections I have, during several years, been endeavouring to trace the minute structure of some of these substances. In no class of materials is it more necessary to guard one's self against errors of observation arising from changes induced in the substance during the operations which are necessary to the preparation of transparent sections of hard substances. Unfortunately, too, it is the custom of the natives to prepare the substance for the market by an imperfect calcination, and hitherto I have only been able to study specimens procured in the markets which have been subjected to this process. It is obviously desirable, before attempting to interpret the structures exhibited under the microscope, to compare the fresh and uncalcined materials with those that have been more or less altered by heat.

Tabasheer would seem, from Brewster's experiments, to be a very intimate admixture of two and a half parts of air with one part of colloidal silica. The interspaces filled with air appear, at all events in most cases, to be so minute that they cannot be detected by the highest powers of the microscope which I have been able to employ. It is this intimate admixture of a solid with a gas which probably gives rise to the curious and anomalous properties exhibited by this singular substance.

The ultra-microscopical vesicles filled with air in all probability give rise to the opalescence which is so marked a property of the substance. Their size is such as to scatter and throw back the rays at the blue end of the spectrum and to transmit those at the red end.

When the vesicles of the substance are filled with Canada balsam, and a thin slice is cut from it, this opalescence comes out in the most striking manner; very thin sections are of a rich orange-yellow by transmitted light, and a delicate blue tint by reflected light.



Section of Indian tabasheer, seen with a magnifying power of 150 diameters.

I do not know of any substance which in such thin films displays such striking opalescence.

That the excessively low refractive power of tabasheer is connected with the mechanical admixture of the colloidal silica with air seems to be proved by the experiments of Brewster, showing that with increase of density there was an increase in the refractive index, from 1·111 in specimens of the lowest specific gravity, to 1·182 in those of the highest specific gravity. Where the surface was hard and dense, Brewster found the refractive index to approach that of semi-opal. The wonderful thing is that a substance so full of cavities containing gas should nevertheless be transparent.

By the kindness of Mr. F. Rutley, F.G.S., I am able to supply a drawing taken from one of my sections of tabasheer.

The accompanying woodcut gives some idea of the interesting structures exhibited in some sections of tabasheer, though much of the delicacy and fidelity of the original drawing has been lost in transferring it to the wood.

In this particular case, the faint punctation of the surface may possibly indicate the presence of air-vesicles of a size sufficiently great to be visible under the microscope. But in many other instances I have failed to detect any such indication, even with much higher powers. The small ramifying tubules might at first sight be taken for some traces of a vegetable tissue, but my colleague Dr. Scott assures me that they do not in the least resemble any tissue found in the bamboo. I have myself no doubt that it is an inorganic structure. It is not improbably analogous to the peculiar ramifying tubules formed in a solution of water-glass when a crystal of copper sulphate is suspended in it, as shown by Dr. Heaton (Proc. Brit. Assoc., 1869, p. 127). Similar forms also occur on a larger scale in some agates, and the artificial cells of Traube may probably be regarded as analogous phenomena.

The aggregates of globular bodies seen in the section so greatly resemble the globulites of slags and natural glasses, and in their arrangement so forcibly recall the structures seen in the well-known pitchstone of Corriegills in Arran, that one is tempted to regard them as indicating the beginnings of the development of crystalline structure in the tabasheer. But I have good grounds for believing the structure to have a totally different origin. They seem in fact to be the portions of the mass which the fluid Canada balsam has not succeeded in penetrating. By heating they may be made to grow outwards, and as more balsam is imbibed they gradually diminish, and finally disappear.

I must postpone till a future occasion a discussion of all the structures of this remarkable substance and of the resemblances and differences which they present to the mineral opals on the one hand, and to those of the opals of animal origin found in sponge spicules, radiolarians, and the rocks formed from them, some of which have recently been admirably investigated by Dr. G. J. Hinde (Phil. Trans., 1885, pp. 425–33).

I cannot, however, but think that it would be of the greatest service to botanists, physicists, and mineralogists alike, if some resident in India would resume the investigations so admirably commenced by Dr. Patrick Russell nearly a century ago; and it is in the hope of inducing someone to undertake this task that I have put together these notes. There are certain problems with regard to the mode of occurrence of this singular substance which could only be solved by an investigator in the country where it is found.

Most parcels of the commercial tabasheer appear to contain different varieties, from the white, opaque, chalk-like forms, through the translucent kinds to those that are perfectly transparent. It would be of much interest if the exact relation and modes of origin of these different varieties could be traced. It would also be important to determine if Brewster was right in his conclusion that the particular internodes of a bamboo which contain tabasheer always have their inner lining tissue rent or injured. The repetition of Dr. Russell's experiment of drawing off the liquids from the joints of bamboos and allowing them to evaporate is also greatly to be desired. My colleague Prof. Rucker, F.R.S., has kindly undertaken to re-examine the results arrived at by Brewster in the light of more recent physical investigations, and I doubt not that some of the curious problems suggested by this very remarkable substance may ere long find a solution.

JOHN W. JUDD

EXHIBITION OF MARINE METEOROLOGICAL INSTRUMENTS

THE eighth Annual Exhibition of the Royal Meteorological Society was held in the Library of the Institution of Civil Engineers, 25 Great George Street, Westminster, from Tuesday, March 15th, to Friday, the 18th. The exhibition was specially devoted to marine meteorological instruments and apparatus, and such new instruments as have been invented and first constructed during the past twelve months.

A very interesting and valuable collection of instruments from the *Challenger* Commission, the Scottish Marine Station at Granton, the Scottish Meteorological Society, and Mr. J. Y. Buchanan, were brought from Edinburgh under the charge of Dr. H. R. Mill, who showed several in action. This set included various forms of deep-sea thermometers, from the early pattern of the Miller-Casella to the Scottish frame for Negretti and Zambra's reversing thermometer, which has been adapted from Magnaghi's by Dr. Mill. Two specimens of the Miller-Casella thermometer, after four months' immersion in brackish water, were shown, with the following results: in No. 1, which was placed at the surface, the copper case was clean, but the scale figures were entirely obliterated from the porcelain; in No. 2, which was suspended in 9 fathoms, and at 1 foot above the bottom, the copper was entirely covered with a green crust, but the scale figures were not rendered illegible. Various forms of piezometers for ascertaining the depth when the temperature is known, or the temperature when the depth is known, were also exhibited. These were nearly all constructed by Mr. Buchanan on board the *Challenger*. Water-bottles for obtaining samples of water at the bottom, or any required depth below the surface, were suspended from the gallery to show their action when in use. The most interesting were Buchanan's sounding-rod and water-bottle for great depths, and Mill's self-locking slip water-bottle for moderate depths.

The Meteorological Council contributed sets of instruments as supplied to merchant ships and the Royal navy; the Royal Meteorological Institute of the Netherlands exhibited a set as supplied to the Dutch navy; and the Deutsche Seewarte sent a set as issued to the German navy.

The Rev. C. J. Steward exhibited a set of instruments as used at the Lochbuie Marine Institute, Isle of Mull, which, among others, included a dimension thermometer in a box for river temperatures, the box being suitable for the bottoms of pools, or rough stony bottoms; and a large disk for ascertaining the transparency of the sea.

In connexion with the deep-sea thermometers Mr. Casella showed some apparatus originally employed in testing these instruments for the Admiralty and the Royal Society, and damaged during the experiments; viz., a bottle broken at a pressure corresponding to 2¼ miles of sea-water, a steel bar bent at 3 miles, and an iron plug broken at 4 miles. Specimens of almost every pattern of deep-sea thermometer were exhibited, including Johnson's registering metallic, the records of which are obtained by the varying expansion of brass and steel bars acting upon indices; Miller-Casella maximum and minimum; and Negretti and Zambra's turnover thermometer.

The barometers exhibited included patterns used in the British, Dutch, French, and German navies. The English marine barometer has an iron cistern and contracted scale, and the gun barometer is mounted with india-rubber packing to prevent breakage caused by gun-firing. MM. Richard Frères, of Paris, sent one of their self-recording aneroids, for use on board ship; and Mr. Abercromby showed several curves taken at sea by one of these instruments in various parts of the world.

The anemometers shown were: Sir Snow Harris's, which is an improved form of Lind's; Hagemann's, Robinson's, Black's pressure, and Whipple's maximum pressure, the latter being quite a new instrument. Dr. Black exhibited his marine rain-gauge and evaporator. Among the miscellaneous instruments were various forms of patent logs, current meters, clinometers, and a model of a section of a vessel fitted with lightning conductor.

In addition to the instruments, a number of charts diagrams, &c., were exhibited, showing the meteorological conditions prevailing over the various oceans of the globe. The advance made in synoptic meteorology over the North Atlantic was clearly shown by comparing Leverrier's charts (1864) with the daily synchronous weather charts just published by the Meteorological Council. The specimens exhibited of the latter were (1) August 1-6, showing the meteorological conditions in the summer; (2) February 9-14, showing the conditions in the winter; and (3) February 24 to March 4, showing the conditions in early spring, and the persistence of the European anticyclone, producing cold dry winds over England. The Meteorological Council also exhibited a set of large charts showing the mean temperature of the sea surface round the coasts of the British Isles for each month. Dr. Mill had several interesting diagrams showing the distribution of temperature in a section of the Clyde sea area at seven periods from April 1886 to February 1887. Mr. Abercromby exhibited forty-six photographs and diagrams of clouds taken in various parts of the world; and Mr. Dyason showed a number of coloured drawings of clouds, &c. The Astronomer Royal sent the photographic registers of magnetic declination and horizontal force at the Royal Observatory, Greenwich, showing the earthquake shock which occurred on the morning of February 23.

The most interesting of the new instruments was the Watkin aneroid with open scale, by Mr. Hicks. Instead of the usual one-circle of figures, the scale of this instrument consists of a spiral of three complete turns. On the aneroid being put under an air-pump or taken up a mountain, the point of the index is gradually drawn *towards* the centre, so that it follows the *decreasing* spiral scale; but when the index moves in the opposite direction, the point moves *away* from the centre, thus following the *increasing* spiral. This is effected by the index-hand being made to slide in and out, so that one end may advance or recede from the centre, and thus follow the spiral scale. Attached to the spindle is a cross-piece, in which the index slides, and a hollow drum fixed to the dial-plate has a flexible chain or cord wound round it, the ends being fastened on the projecting pins riveted to the index. Consequently, if the spindle and the piece attached to it are revolved, one portion of the chain or cord winds off the drum, the other is wound on to the same extent, and the index is caused to slide through the cross-piece, the direction of motion being controlled by the direction in which the spindle is revolved.

MM. Richard Frères sent specimens of their self-recording thermometer, hygrometer, dry and wet bulb thermometers, and rain-gauge.

GEOGRAPHY AT THE UNIVERSITIES

AT last, after years of apparently fruitless labour, the Royal Geographical Society have been eminently successful in persuading almost simultaneously the two great English Universities to recognise geography as a University study, and to make definite provision for teaching it. In pursuance of a proposal made by the President and Council of the Royal Geographical Society to the Vice-Chancellors of the two Universities, and of the replies thereto, a deputation of a few members of their Council visited Oxford and Cambridge in turns, to meet delegates appointed by those Universities, in order to explain their proposal more fully, and to discuss any modifications that might be suggested. The main features of the proposal were, that the Royal Geographical Society offered to give 150*l.* annually to each University if they would establish a Lectureship or Readership in Geography, giving the Lecturer an adequate University status, and contributing, on their part, an equal sum, so as to raise the stipend of each Lectureship to 300*l.* They also offered to give the two Universities a Scholarship or Exhibition of 100*l.* in alternate years for geographical students. The Royal Geographical Society was to be represented on the Board that selected the Examiners, and on that which adjudged the Scholarship.

The meeting at Oxford with delegates from that University, including the present and past Vice-Chancellors, took place five weeks ago, at which the proposal was well discussed and favourably entertained, subject to the foreseen difficulty of finding adequate funds from the University resources; nevertheless everything seemed in train for its being eventually carried out, though after a little delay, in the intended manner. An unexpected incident, however, gave a new and collateral impulse, and has hurried the Lectureship into existence at once. It happened that the Readership in Ancient History became vacant, and it seems to have occurred to those with whom the election of a successor rested, that as there was a great difficulty in finding funds for geography, and as a Professorship of Ancient History was already in existence, and, again, as ancient history was taught by most classical tutors, the Readership in Ancient History might be abolished without much loss, and one in geography might be with propriety established in its place. There was a nearly even division of opinion on the matter, but the vote for geography prevailed and carried the day, and the advertisement inviting candidates has already been published. So Oxford now takes an independent line, and accepts only the offer of the Scholarship.

The Cambridge meeting took place about three weeks ago. The proposal was carefully discussed, and modifications were asked for. At Cambridge, as at Oxford, the University funds are seriously embarrassed by engagements already entered into, chiefly connected with building operations; and there seemed no way, so narrow was the available surplus, of raising the whole of the annual amount of 150*l.* in a direct form, but only 50*l.* of it. However, it appeared that indirect means existed by which this nominal sum would indirectly and eventually be raised to even something more than the proposed amount, and an amendment specifying only 50*l.* was therefore provisionally accepted. After this had received the approval of the Council of the Royal Geographical Society, it was submitted to the Council of the University of Cambridge, and adopted by them in the terms of the following recommendation:—

"That the approval of the Senate be given to the delivery in the University in the ensuing academical year of one or more courses of lectures on geography by lecturers selected by the Royal Geographical Society, that a teacher of geography be appointed by a Committee on which the Royal Geographical Society is represented, and that the Senate accept the proposal of the Royal Geographical Society to award in alternate years an Exhibition of 100*l.* or prizes of 50*l.* and 25*l.* That before the end of the Easter Term, 1888, a University Lecturer in Geography be appointed, for a period of five years, at a stipend of 200*l.* a year, of which sum 50*l.* is to be paid out of the common University fund and 150*l.* by the Royal Geographical Society. The appointment of the Lecturer to be made by a joint Committee of the representatives of the Royal Geographical Society and of the Council of the Senate, subject to the confirmation of the Senate; the Lecturer to submit his scheme of lectures to the Committee of Management; and power is to be given to the Council of the Senate, with the concurrence of the Committee of Management, to cancel the appointment of the Lecturer at any time."

This recommendation has to be submitted to the Senate at the beginning of next term, but its ultimate acceptance is placed almost beyond doubt through the very favourable reception given to the proposals of the Royal Geographical Society by the Council of the University.

THE ORGANISATION OF INDUSTRIAL EDUCATION

THE following is the letter by Prof. Huxley to which reference is made in our leading article (p. 482):—

"When a statesman of Lord Hartington's authority concurs with and enforces the opinions I ventured to express some little time ago, I have every reason for private and personal satisfaction. But the circumstance has a public importance as evidence that our political chiefs and leaders are giving their serious attention to those social questions which lie far above the region of party strife, and are of infinitely greater moment than the topics which ordinarily absorb the attention of politicians.

"The organisation of industrial and commercial education is not the least of these great problems. That it has to be solved, under penalty of national ruin, proves to be no mere alarmist fancy, but the belief of an experienced man of affairs, whose imperturbable coolness and strong common-sense are proverbial.

"It is an interesting question for us all, therefore, How do we stand prepared for the task thus imperatively set us? My conviction is that we are in some respects better off than most people imagine, in others worse. I conceive that two things are needful: on the one hand, a machinery for providing instruction and gathering information; on the other hand, a machinery for catching capable men wherever they are to be found and turning them to account. Now, I apprehend that both these kinds of machinery are to be found, though in a fragmentary and disconnected condition, in several organisations which, though independent, supplement one another.

"The first of these is that of the School Boards, which provide elementary education, and sometimes, though too rarely, have at their disposal scholarships by which capable scholars can attain a higher training. The second is the organisation of the Department of Science and Art. The classes, now established all over the country in connexion with the Department, not only provide elementary instruction, accessible to all, but offer the means whereby the pick of the capable students may obtain in the schools at South Kensington as good a higher education in science and art as is to be had in the country. It is from this source that the supply of science and art teachers, who in turn raise the standard of elementary instruction, is derived. The third organisation is that of the technical classes connected with the City and Guilds Institute, or with the Society of Arts, or with provincial Universities and Colleges, which provide special technical instruction for those who have, or ought to have, already acquired the elements of scientific and artistic knowledge in the science and art classes.

"A fourth organisation for the advancement of the interests of industry and commerce, of the nature of that which I imagined it was the intention of the founders of the Imperial Institute to create, and such as is, I believe, now actually in course of creation in the City of London, will complete the drill-grounds of the army of industry, and, so far as I can judge, omit nothing of primary importance. But, leaving the last aside as still in the embryonic condition, these excellent organisations are all mere torsos, fine—but fragmentary.

"The ladder from the School Boards to the Universities, about which I dreamed dreams many years ago, has not yet acquired much more substantiality than the ladder of Jacob's vision.

"The Science and Art Department has done, and is doing, admirable work, which I regret to see more often made the subject of small and carping criticism than of the praise which is its due. I trust it may not be diverted from efficiently continuing that work by having duties for which it is unfit forced upon it. That which the Department needs, in my judgment, is nothing but the means of doing that which Commission after Commission, Royal and departmental, have declared to be its proper business.

"As Dean of the Normal School I may be permitted to declare that it is impossible for us to perform the functions allotted to us unless the recommendations made by impartial and independent authority are carried into effect.

"The school exists, and common-sense surely suggests either make it efficient or abolish it. The alternative of abolition is not likely to be adopted, as that step would be equivalent to striking the keystone out of the edifice of scientific instruction for the masses of the people which it has taken a quarter of a century to raise, and which is the essential foundation for any sound system of technical education. The alternative of efficiency means spending a few thousand pounds on additional buildings; but the guardians of the national purse do not seem to feel the force of the adage about 'spoiling a ship for a halfpenny-worth of tar.'

"The state of affairs in regard to that which ought to be the centre of our system of technical education is nearly the same. The Central Institute is undoubtedly a splendid monument of the munificence of the City. But munificence without method may arrive at results indistinguishably similar to those of stinginess. I have been blamed for saying that the Central Institute is 'starved.' Yet a man who has only half as much food as he needs is indubitably starved, even though his short rations consist of ortolans and are served up on gold plate. And I have excellent authority for saying that little more than one-half of the plan of operations of the Institute, drawn up by the Committee of which I was a member, has been carried out, or can be carried out, if the funds allotted for the maintenance of the Institute are not largely increased. At the same time, the Institute is doing all that could be rationally expected of it. Some of the guilds and many provincial towns are making admirable provision for elementary technical education. Such work, in my judgment, ought to be left to local administrators, whatever aid it may be thought desirable to give them. But the local schools should be brought into relation with the Central Institute, and this should be put upon such a footing as to subserve its proper purpose of training teachers and giving higher technical instruction.

"Economy does not lie in sparing money, but in spending it wisely. And it is, to my mind, highly necessary that some man or body of men, whom their countrymen trust, should consider these various organisations as a whole and determine the manner in which they should be correlated and in which it is desirable that the resources, public and private, which are available should be distributed among them.

"Lord Hartington has many claims on the gratitude and respect of his countrymen. I venture to express the wish that he would add to them by taking up this great work of organising industrial education and bringing it to a happy issue."

AUGUST WILHELM EICHLER

THE death of Dr. August Wilhelm Eichler, briefly announced in a previous number, is a great loss to botanical science, and especially to systematic botany. Year by year we are losing men of wide and consequently sound knowledge of plants without their places being adequately filled. We have doubtless arrived at a stage in botany where specialists are necessary; yet we venture to assert that men of general attainments are better qualified than specialists, in a narrow sense, for the head of large botanical establishments, such as the one over which the late Dr. Eichler presided, and which greatly extended its reputation during the nine years he was Director.

Dr. Eichler was barely forty-eight years of age, but before entering upon the absorbing duties connected with the University and Botanic Garden of Berlin he had already made a name as a botanical author.

For some years he was assistant to Von Martius at Munich, and succeeded him as editor of the colossal "Flora Brasiliensis," now nearly completed. This was in 1868, but he had previously been a considerable and excellent contributor to this work, having elaborated several difficult families in a masterly manner. The work by which he is more generally known is the "Bluthendiagramme," in which he admirably illustrates and explains the morphology and organogeny of the Phanerogamia. His labours were chiefly in the direction of morphology. His continued careful study of the female flower of the Coniferæ may be regarded as having finally settled the homologies of the different elements of the inflorescence of that family. One of his later contributions to science, if not his last, is entitled "Zur Entwickelungsgeschichte der Palmenblatter," in which the author fully elucidates the development of the various types of leaf in the Palmæ.

As a lecturer Dr. Eichler was exceedingly popular and successful; and he was regarded as an able administrator of the Botanic Garden. He was successively Professor of Botany at Munich, Gratz, Kiel, and Berlin, having been appointed to the last post in 1878. Two years later, "at the comparatively youthful age of thirty-nine," he was chosen a member of the Berlin Academy of Sciences; and in 1881 he was elected Foreign Member of the Linnean Society of London. He was also honorary and corresponding member of many other learned societies; and all who knew him, however slightly, will join in regretting his early death.

NOTES

BARON EGGERS, commissioned by Dr. Urban and assisted by the Royal Academy of Sciences of Berlin, is about to undertake the botanical investigation of the hitherto unexplored higher mountains of St. Domingo The specimens collected for distribution will be arranged (under corresponding numbers) in two series. One will consist only of species which have not yet been distributed in Baron Eggers' West Indian collections; the other and larger series will include everything except the commonest tropical species. The first-named series will be disposed of at forty shillings per century, the latter at thirty shillings. Dr. J. Urban, assisted by other systematists, will determine the collections and receive the names of subscribers. As the expense and difficulty of transit in the island must limit the number of collections for sale, early application to Dr Urban is desirable. Dr. Urban's address is Friedenau, bei Berlin.

A CONVERSAZIONE given by the Council of the City and Guilds of London Institute was held at the Central Institution, Exhibition Road, on Wednesday evening, the 16th inst, and was attended by about 1300 visitors. Lord Selborne received the guests. A large number of interesting objects of scientific and artistic interest were exhibited, and during the evening demonstrations were given by the Professors in the various departments, as well as by several gentlemen who are associated with the work of the Institute.

ON the 15th inst. a meeting was held at Grimsby to consider the expediency of establishing there an Institution for Technical Education with regard to Fish and Fisheries, and a Marine Fish-Culture Station. Mr. W. Oldham Chambers, Secretary of the National Fish-Culture Association, pointed out to the meeting the advantages of the proposed Station and Institute. Resolutions in support of the scheme were unanimously adopted, and an influential local Committee was appointed to further the object in view. Letters have been received from the various Fish Trade Associations and other bodies, heartily approving of the undertaking. The Manchester, Sheffield, and Lincolnshire Railway Company are prepared to grant a site for the Institute, and to erect a building, free of cost, at Cleethorpe, near Grimsby.

WE are sorry to see that the income of the Mason Science College, Birmingham, during the year ending "Founder's Day," February 23, fell short of the expenditure by the sum of 1646*l*. After deducting what may be termed extraordinary expenditure, there remained a deficiency of 1074*l*. The Council, in their last report, remind the Trustees that the annual deficits, which since 1831 have been charged against the accumulated surplus, have now reduced this fund to the sum of 1419*l*., and that the estimates for the current financial year anticipate that the balance of the fund will be required. It is not creditable to the well-off citizens of Birmingham that an institution capable of doing great work for their town and district should have to meet these constantly recurring deficiencies.

THE spring meeting of the Institution of Mechanical Engineers, under the presidency of Mr. E H. Carbutt, will take place on Monday, May 16, and the following day. On Tuesday, May 17, the Duke of Cambridge will dine with the members of the Institution

IN order to determine between the rival sites for the Sedgwick Memorial Museum at Cambridge, and at the same time advance the chances of proceeding early with a portion at least of the building, the Council of the Senate propose to submit a grace next term to settle the question of site. The grace will take the form of authorising negotiations with Downing College for a site opposite the old Botanic Garden. If this be rejected, the latter affords the only practicable site.

MISS GORDON has presented to the Museum of the Royal Gardens, Kew, the collections and drawings made by her late brother, General Gordon, illustrative of the Coco de Mer (*Lodoicea seychellarum*), a palm peculiar to the Seychelles, and remarkable, among other things, for possessing the largest known seed in the vegetable kingdom. The seeds are well known in European museums. One amongst General Gordon's specimens is a model which he had made of the fruit in its mature state, before the external fibrous but perishable husk had become detached. Some of the specimens are placed, with others already possessed by Kew, in No. 2 Museum The rest will be shown, with the drawings made by his own hand, in No. 3 Museum.

THE Cambridge University Local Examination Report for the past year states that in zoology and physiology the answers showed very inefficient teaching. Botany is somewhat better done; but many senior candidates had not been taught the use of floral diagrams In physical geography, while the answering was generally good, many had used antiquated text-books. Chemistry was fairly done, the candidates choosing, out of the alternative questions, the practical rather than the theoretical. Qualitative analysis was well done, both by seniors and juniors. The seniors showed general ignorance about the laws of multiple proportion, and combination by volume. Heat was badly done by both seniors and juniors. Many seemed never to have read any text-book, and to have presented themselves on the strength of a few isolated facts. Statics was very unequally mastered. There was better acquaintance with the mathematical than with the practical part of the subject. Electricity (senior subject) had not been studied seriously enough to warrant its inclusion in the examination. The mathematical subjects of the examination are reported on much more favourably.

The botanical collections of the late Thomas Moore, F.L.S. Curator of the Botanic Garden at Chelsea, belonging to the Society of Apothecaries, have been acquired for the Herbarium of the Royal Gardens, Kew. The most important portions are:—(1) The general fern herbarium, which contains the types of the numerous species described by Moore, especially those introduced into European cultivation. (2) The collection of forms and varieties of British ferns, which is probably unique in richness and completeness; it is especially interesting as the basis of Mr. Moore's well-known and beautifully illustrated works on the fern flora of the British Isles. (3) The fern herbarium of R. Heward, F.L.S., which is especially strong in West Indian species.

British field botanists will be glad to learn that the Scottish Rights of Way Society has been successful in its action brought in the Court of Session against the proprietor of Glen Doll in Clova. Lord Kinnear has found that "the pursuers had established a sufficient use and possession of the road for more than forty years to entitle them to a judgment." There is probably no portion of the Highlands of Scotland from which botanists would feel it a greater hardship to be excluded. For years it has been so well watched by keepers that access to it has been impossible, except to such botanists as are swift and sure of foot. The present owner is the first who has denied a right of way through it, and, if we are not mistaken, the action only concerns this right to use the road. It is to be feared that efforts will not be wanting to confine the public to the road, and to deny all access to those parts so interesting to the field botanist.

A series of charts showing the surface temperatures of the Atlantic coast waters, from the eastern coast of Maine to the extreme southerly coast of Florida, is being prepared by the United States Fish Commission. The Commission is aided in this important undertaking by the Lighthouse Board and the Signal Service. Observations have thus far been made at twenty-four lighthouse stations, showing the surface temperatures at these localities during the past five years. The temperatures at each station are shown in detail for each year by ten-day means, and the facts are combined with those brought out on a series of isothermal charts giving the relations of the different stations. The results are likely to be of great value in connexion with the study of the migration of the mackerel, menhaden, shad, and other migratory fishes.

An interesting discussion has just been started in the Paris Academy of Medicine, concerning the bad results of mental straining in young persons. Attention has especially been called to the fact that many French girls, under the pressure of competition, are injuring their health by over-work at school. About 12,000 of them are trying to get the superior diploma which would confer upon them the right of getting an appointment in Government schools. Only 2000 will be able to get appointments.

An excellent address on the physical training of girls was lately given by Dr. Rayner W. Batten to the Gloucestershire branch of the British Medical Association. It is printed in the *British Medical Journal*. Speaking of ladies' Colleges, Dr. Batten says he does not know of more than one that has such a thing as a proper playground, whilst a leading College, if not the first in the country, with abundant means and ample opportunities, makes no pretence of having any playground at all. Dr. Batten urges that drill and calisthenic exercises are not enough. There must be recreation as well, "and at present, in our ladies' Colleges," he says, "the exercise, with the exception of tennis, has little of the recreative element in it." Dr. Batten is of opinion that all Colleges should have playgrounds—large spaces, open to the fresh air and sunlight—that every girl should be made to play, two half-holidays a week at least being given for that purpose, and that the games should be varied, so that girls may not have to go on doing what they are conscious of not doing well. "Every girl will soon find out her strong and weak points in play as well as in work, and if the game is to be a recreation she must be allowed to choose her own form, the only obligation being that she is to play, and that no books or work are to be brought on the playground."

At the meeting of the Essex Field Club on Saturday next, the 26th inst., Prof. Sylvanus P. Thompson will read a paper on William Gilbert, the founder of the science of electricity, and an Essex worthy entitled to rank with Ray among the pioneers of science. Those wishing to attend the meeting should communicate with the Secretary, Buckhurst Hill, Essex.

On the night of March 7, about 11.30, a brilliant meteor was seen in Dalcarlia, in Central Sweden. It was first seen in the north-west, going in a southerly direction, but soon afterwards it changed its course more easterly. Its colour was a brilliant white, and its greatest size about that of the moon. It was lost to sight behind the horizon, leaving only a faint trail behind.

From a recent official French Report on oyster-culture in France we learn that the two principal centres are at Arcachon in the south-west and Auray in the north-west. The Bay of Arcachon has since 1854 held a foremost place in oyster-breeding. In 1857 there were twenty parks, or district oyster-beds: in 1865 the number had increased to 297, with an output of over 10,000,000 oysters. At the present time the little bay, which has a total area of 37,500 acres, has oyster-beds covering an area of 15,000 acres, which provide annually about 300,000,000 oysters for consumption. With regard to the oyster-beds at Auray, on the coast of Brittany, these, though not so important as those of Arcachon, have still a considerable output, and, from being exhausted and unproductive when their rehabilitation was first undertaken, have become full to overflowing. In 1876–77 we find that 7,000,000 oysters were placed on the market from Auray; in 1885 the number had risen to over 70,000,000.

The ideas of M. Victor Meunier with regard to the domestication of apes are discussed in the new number of the *Revue d'Anthropologie* by Madame Clémence Royer, the French translator of Darwin. Madame Royer does not doubt that, under a proper system of training, apes might be made good workers. They lack perseverance, indeed, but in general intelligence they are, she thinks, superior to the dog, the horse, or even the elephant. She points out, however, that it would be necessary to feed domesticated apes with great quantities of fruit, bread, and eggs, that the process of educating them would be costly, and that for many generations they would probably be injuriously affected by the climate of Europe. Her opinion is that, if the experiment is to be made, it should be made first of all in tropical countries, where apes might be taught to labour in connexion with the cultivation of coffee, cocoa, and cotton.

An interesting paper on "The Application of Gems to the Art of the Goldsmith" was read to the Society of Arts on Tuesday, the 15th inst., by Mr. Alfred Phillips. It is printed in the Society's Journal. Mr. Phillips gives a very favourable account of the capacity of English workmen employed by goldsmiths at the present day. When masters encourage them to depart from the beaten track, they readily adapt themselves, Mr. Phillips says, to work which, ten years ago, would have been sent as a matter of course to specialists on the Continent.

A HEALTH EXHIBITION will be opened in Warsaw on May 15 next.

AN International Agricultural Exhibition of Tools and Implements will be held at Parma in September next.

THE Royal Bavarian Academy of Sciences is collecting the numerous treatises of Joseph Fraunhofer, hitherto dispersed in numberless serials, and is about to publish them in one volume.

PROF. VERNEUIL AND L. H. PETIT have issued the first number of a periodical publication called "Études expérimentales et cliniques sur la Tuberculose." It is published by means of a fund especially raised for the promotion of the study of tuberculosis.

M. H. GADEAU DE KERVILLE has just published a work on evolution. It is entitled "Causeries sur le Transformisme," and contains an exposition of the facts and theories upon which the doctrine of evolution is based.

A BOOK on therapeutics, by M. G. Hayem, Professor in the Paris Medical School, has just been published.

THE February number of the Italian Geographical Bulletin contains a detailed account, by Dr. G. A. Colini, of the rich ethnological collection recently presented to the Prehistoric and Ethnographic Museum of Rome by General Genè, Commander of the Italian possessions on the East Coast of Africa. The collection includes a great variety of objects, such as arms, costumes, implements, ornaments, utensils from Abyssinia, Somali Land, and the Afar (Danakil) country. Amongst them are baking-ovens, braziers, incense-burners, cooking-utensils, pestles for grinding coffee, pepper, durrha, &c.; baskets, matting, veils, robes, loin-cloths, wooden sandals, lamps, swords, matchlock guns, knives, hairpins, &c., illustrating the arts and industries of the East African peoples.

WE have received the four latest Bulletins of the U.S. Geological Survey (Nos. 30–33). No. 30 contains Mr C. D. Walcott's second contribution to "Studies on the Cambrian Faunas of North America." A systematic review of our present knowledge of fossil insects, including myriapods and arachnids, by Mr. S. H. Scudder, is presented in No. 31; and an elaborate account of mineral springs of the United States, by Dr. A. C. Peale, in No. 32. No. 33 is made up of notes, by Mr. J. S. Diller, on the geology of Northern California.

MR. EDWARD COOKWORTHY ROBINS, whose collected papers on technical education and applied science, buildings and fittings, &c., were reviewed in NATURE some time ago, is now engaged on a general work of reference on the same subject. It will appear shortly under the title of "Technical School and College Buildings," in a quarto volume of about 250 pages, with upwards of 100 full-page illustrations, plates, and maps.

IN the Proceedings of the American Antiquarian Society (vol. iv. p. 62) Mr. Frederick W. Putnam gives an account of twelve jade objects found in Nicaragua and Costa Rica, ten of which were ornaments made by cutting celts into halves, quarters, or thirds, a portion of the cutting edge of the celt remaining on each piece. Mr. O. W. Huntington who was asked to report upon the nature and source of the material of these ornaments, is of opinion that the specimens 'are unquestionably Chinese jade." They have, he says, "all the characters of that mineral, although the largest specimen from Costa Rica is rather unusual in its colour, and would not be taken for jadeite at sight." The *American Naturalist*, which calls attention to these facts, thinks "it will now be in order to collate during the next ten years the evidence for and against contact between the Orient and the western shores of America."

SOME interesting notes from Venezuela have lately been contributed by Dr. Ernst, of Caracas, to the Proceedings of the Berlin Anthropological Society. The writer brings together much valuable information as to the manners and customs of the aboriginal population, and about their food, ornaments, implements, weapons, and canoes.

THE additions to the Zoological Society's Gardens during the past week include a Mange's Dasyure (*Dasyurus maugei* ♀) from Australia, presented by Mr. W. Miller; two White-crowned Pigeons (*Columba leucocephala*) from the West Indies, presented by Lieut.-Colonel Dawkins; two Long-tailed Grass Finches (*Poephila acuticauda*) from Australia, presented by Mr. Walter Burton; an Algerian Tortoise (*Testudo mauritanica*) from North Africa, presented by Mr. J. M. Green; a European Pond Tortoise (*Emys europaea*), South European, presented by Mr. Henry Garle; five European Tree Frogs (*Hyla arborea*), European, presented by Mr. F. W. Green; an Axis Deer (*Cervus axis* ♀), a Collared Fruit Bat (*Cynonycteris collaris*), sixteen Puff Adders (*Vipera arietans*), born in the Gardens.

OUR ASTRONOMICAL COLUMN

RESEARCHES ON THE DIAMETER OF THE SUN.—Herr Auwers has published in the *Sitzungsberichte der Königlich Preussischen Akademie der Wissenschaften zu Berlin*, 1886, No. I., the first part of an elaborate investigation of the value of the sun's diameter as found from meridian observations, and of the apparent variations thereof. The discussion now published refers to variations in the mean annual values only of the diameter. The series of observations discussed are the meridian observations of the sun made at Greenwich, 1851–83; at Washington, 1866–82; at Oxford (Radcliffe Observatory), 1862–83; and at Neuchâtel (transit observations only), 1862–83. The "personal equations" of the various observers are first determined on the supposition that there may be periodic annual variations, both in the horizontal and vertical diameters of the sun, such for instance as have been supposed by Secchi and others to exist, with a period corresponding to the sunspot cycle. The first determination of "personal equation" is therefore made by comparing observations taken in each year with others taken in the same year only. The resulting diameters are, however, such as to convince Herr Auwers that, although inequalities exist in each of the series of observations discussed, their comparison with each other and with the sunspot curve is sufficient to show that they have no connexion either with the latter or with a progressive change, but are most probably due to uncorrected "personal equations." A second determination of these on the assumption that, for some observers at least, they are liable to change, but that the sun's diameter is not subject to annual variation, leads to much more satisfactory results, and is regarded by Herr Auwers as the correct solution of the problem. The effect of personality on the deduced solar diameter, which on the average, for an individual observer, amounts to about 1″ (sometimes 3″, 4″, and even 10″), may be inferred from the fact that the values of the horizontal and vertical diameters of the sun, deduced from thirty-three years' observation with the Greenwich transit-circle, and referred to the mean of Dunkin, Ellis, Criswick, and J. Carpenter, as standard, are respectively 32′ 2″·48 and 32′ 2″·00; whilst, referred to the mean of fifty-four observers, the same observations give, for the horizontal and vertical diameters respectively, the values 32′ 1″·99 and 32′ 2″·73.

COMET 1887 *e* (BROOKS, JANUARY 22).—The following ephemeris for Berlin midnight, is by Dr. R. Spitaler (*Astr. Nach.* No. 2776).

1887	R.A.	Decl.	Brightness
	h. m. s.	° ′	
March 24	4 18 8	35 46·5 N.	0·72
26	4 21 20	34 26·1

The brightness on January 24 is taken as unity.

MINOR PLANET No. 262.—This object has received the name of Valda.

HARVARD COLLEGE OBSERVATORY.—The late Uriah A. Boyden having left propretty to the value of 230,000 dollars in trust for the purpose of astronomical research, the Trustees of the fund have transferred the property to the President and Fellows of Harvard College, in order that the researches proposed by Mr. Boyden may be directed at the Harvard College Observatory. These researches will be supported by a portion of the means of the Observatory, in addition to the trust fund itself. By the terms of the will the money is to be devoted to observations "at such an elevation as to be free, so far as practicable, from the impediments to accurate observations which occur in the observatories now existing, owing to atmospheric influences."

ASTRONOMICAL PHENOMENA FOR THE WEEK 1887 MARCH 27—APRIL 2

(FOR the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is here employed.)

At Greenwich on March 27

Sun rises, 5h. 49m.; souths, 12h. 5m. 30·1s.; sets, 18h. 22m.; decl. on meridian, 2° 35′ N.: Sidereal Time at Sunset, 6h. 41m.

Moon (at First Quarter on April 1) rises, 7h. 19m.; souths, 14h. 12m.; sets, 21h. 16m.; decl. on meridian, 9° 44′ N.

Planet	Rises	Souths	Sets	Decl. on meridian

GEOGRAPHICAL NOTES

IN a recently-issued Colonial Office Report on the Gambia will be found some useful data on the climate of that colony which completely upset the results of previous observations and greatly reduce the temperatures hitherto accepted. The mean temperature, according to these latest observations, varies from 68°·5 in January to 80° in July at 7 a.m., and from 73°·7 in January to 82°·5 in July at noon. The same Report contains some interesting statements relating to the ethnology of the colony.

THE principal paper in the just-issued Bulletin (only No. 4 of 1885) of the American Geographical Society is on the historical and geographical features of the Rocky Mountain Railways, by Mr. James Douglas. There is also a translation of Baron Nordenskjold's reply to criticisms on the "Voyage of the *Vega*." The criticisms relate to points of minor importance.

THE new number of the "Antananarivo Annual and Madagascar Magazine" (Christmas, 1886), consists, besides a reprint of Mr. A. R. Wallace's chapter on the fauna of Madagascar, mainly of papers on linguistic topics and on Malagasy folk-lore. M. Grandidier's paper on the channels and lagoons of the east coast of the island is translated with some interesting remarks by Mr. Sibree appended. Mr. Sibree points out that it would only require about thirty miles of canals to connect all these lagoons and so create a safe and extensive internal waterway of the greatest commercial value. The Rev. W. Montgomery contributes a paper on the Malagasy game of "Fanerana," in many respects resembling chess.

IN the new number (Heft i. Band 10.) of the *Deutsche Geographische Blatter*, we find a useful and careful, if rather too favourable, study of the trade-routes of Mexico, old and new, and their commercial importance, by Herr A. Scobel. From a scientific point of view the most valuable paper is that of Dr. Otto Finsch on his visit three years ago to the atoll of Diego Garcia in the Chagos Archipelago, about half-way between the Seychelles and Ceylon. Dr. Finsch was only a few hours on the islands, but his notes on the people (mostly of the Negro type from the Mauritius) and the richness of the bird life are interesting. An open space in the little east island was covered with "millions" of birds, whose combined cry was deafening. Eggs, also in "millions," lay about everywhere, unprotected by any nest. The commonest among these birds was the sooty tern (*Sterna fuliginosa*). Next to the Laccadives, the Chagos Islands seem to be the favourite breeding-place of this bird in the Indian Ocean. The variety in the colouring of the eggs was unprecedented in Dr. Finsch's experience, especially considering the fact that they all belonged to birds of the one species named above. The only other species noticed in the island by Dr. Finsch was the noddy (*Anous stolidus*). The birds arrive in the islands in the month of June, and stay till the young are fledged; by November they have all taken their departure. As on most coral islands, the animal world generally is very poor.

THE same number contains an account of Fontana's exploration of Eastern Patagonia in 1885, and also a short biography of Emin Pasha. From the latter we learn that Edward Schnitzer was born at Oppeln, in Silesia, in 1840; received his early education at Neisse, in Upper Silesia, and studied medicine at Breslau, Berlin, and Königsberg. From his earliest years he had a special taste for natural history, and especially ornithology, and in the latter department he has all along been a diligent collector. In 1864 we find Schnitzer at Antivari, in Albania, as a surgeon in the Turkish service. In 1870 he accompanied Ismail Pasha to Syria and Arabia, and afterwards to Trebizond, Erzeroum, and Epirus. At Ismail's death in 1874, Schnitzer came to Constantinople, and in 1875 made a short visit to his German home. Entering the Egyptian service, he, in 1876, followed Gordon Pasha from Cairo into the Soudan, where, under the title of Emin Effendi, he was appointed chief surgeon, and in 1878 Governor-General of the Equatorial Province, with the title of Bey. His work as administrator, scientific explorer, and collector, since then is well known. To Bremen and Vienna he has sent some 2000 bird-skins, carefully labelled with all necessary information, and including some twenty-five new species.

SINCE the time of Herodotus travellers in Africa have brought home reports of pygmy tribes scattered about in various regions of Africa. Readers of Schweinfurth will remember the Akkas whom he met in the Monbuttu country, and now Dr. Ludwig Wolf, who, with Wissmann, recently explored the Sankuru, the great southern tributary of the Congo, gives us many details of a similar pygmy race among whom he sojourned for some time, in the district to the north-west of the station Luluaburg. He found entire villages inhabited by tiny men and women, of a height of not more than 1·40 metre. Among their neighbours they are known as Batua. These are nomad tribes devoting themselves exclusively to the chase and the manufacture of palm wine. Their villages, consisting of huts, are met with in clearings in the forests which cover the greater part of the country. Each district thus possesses a village of pygmies. As is the case of the Akkas among the Monbuttus, so the Batua among the Bakubu are regarded as little benevolent beings whose special mission is to provide the tribes among whom they sojourn with game and palm-wine. In exchange, manioc, maize, and bananas are given to the pygmies. Generally they live apart, but sometimes they unite themselves with races of larger stature. They excel in the art of scaling palm-trees to collect the sap, and in setting traps for game. Their agility is almost incredible. In hunting they bound through the high grass like grasshoppers, facing the elephant, antelope, and buffalo with the greatest audacity, shooting their arrows with rare precision, following up rapidly with a stroke of the lance. Physically the Batua are very well made, having absolutely no deformity. They are simply little men, well proportioned, very brave, and very cunning. Their mean height is 1·30 metre. Their skin is a yellow-brown, less dark than that of larger races. Their hair is short and woolly. Neither the Akkas nor the Batua have any beard.

SUNLIGHT COLOURS[1]

SUNLIGHT is so intimately woven up with our physical enjoyment of life that it is perhaps not the most uninteresting subject that can be chosen for what is—perhaps somewhat pedantically—termed a Friday evening "discourse." Now, no discourse ought to be possible without a text on which to hang one's words, and I think I found a suitable one when walking with an artist friend from South Kensington Museum the other day. The sun appeared like a red disk through one of those fogs which the east wind had brought, and I happened to point it out to him. He looked, and said, "Why is it that the sun appears so red?" Being near the railway station, whither he was bound, I had no time to enter into the subject, but said if he would come to the Royal Institution this evening I would endeavour to explain the matter. I am going to redeem that promise, and to devote at all events a portion of the time allotted to me in answering the question why the sun appears red in a fog. I must first of all appeal to what everyone who frequents this theatre is so accustomed, viz. the spectrum; I am going not to put it in the large and splendid stripe of the most gorgeous colours before you with which you are so well acquainted, but my spectrum will take a more modest form of purer colours some twelve inches in length.

I would ask you to notice which colour is most luminous. I think that no one will dispute that in the yellow we have the most intense luminosity, and that it fades gradually in the red on the one side and in the violet on the other. This then may be called a qualitative estimate of relative brightnesses; but I wish now to introduce to you what was novel last year, a quantitative method of measuring the brightness of any part.

Before doing this I must show you the diagram of the apparatus which I shall employ in some of my experiments.

R R are rays (Fig. 1) coming from the arc light, or, if we were using sunlight, from a heliostat, and a solar image is formed by a lens, L_1, on the slit S_1 of the collimator C. The parallel rays produced by the lens L_2 are partially refracted and partially reflected. The former pass through the prisms P_1P_2, and are focused to form a spectrum by a lens, L_3, on D, a movable ground glass screen. The rays are collected by a lens, L_4, tilted at an angle as shown, to form a white image of the near surface of the second prism on F.

Passing a card with a narrow slit, S_2, cut in it in front of the spectrum, any colour which I may require can be isolated. The consequence is that, instead of the white patch upon the screen, I have a coloured patch, the colour of which I can alter to any hue lying between the red and the violet. Thus, then, we are able to get a real patch of very approximately homogeneous light to work with, and it is with these patches of colour that I shall have to deal. Is there any way of measuring the brightness of these patches? was a question asked by General Festing and myself. After trying various plans, we hit upon the method I shall now show you, and if anyone works with it he must become fascinated with it on account of its almost childish simplicity—a simplicity, I may remark, which it took us some months to find out. Placing a rod before the screen, it casts a black shadow surrounded with a coloured background. Now I may cast another shadow from a candle or an incandescence lamp, and the two shadows are illuminated, one by the light of the coloured patch and the other by the light from an incandescence lamp which I am using to-night. [Shown.] Now one stripe is evidently too dark. By an arrangement which I have of altering the resistance interposed between the battery and the lamp, I can diminish or increase the light from the lamp, first making the shadow it illuminates too light and then too dark compared with the other shadow which is illuminated by the coloured light. Evidently there is some position in which the shadows are equally luminous. When that point is reached, I can read off the current which is passing through the lamp, and having previously standardised it for each increment of current; I know what amount of light is given out. This value of the incandescence lamp I can use as an ordinate to a curve, the scale number which marks the position of the colour in the spectrum being the abscissa. This can be done for each part of the spectrum, and so a complete curve can be constructed which we call the illumination curve of the spectrum of the light under consideration.

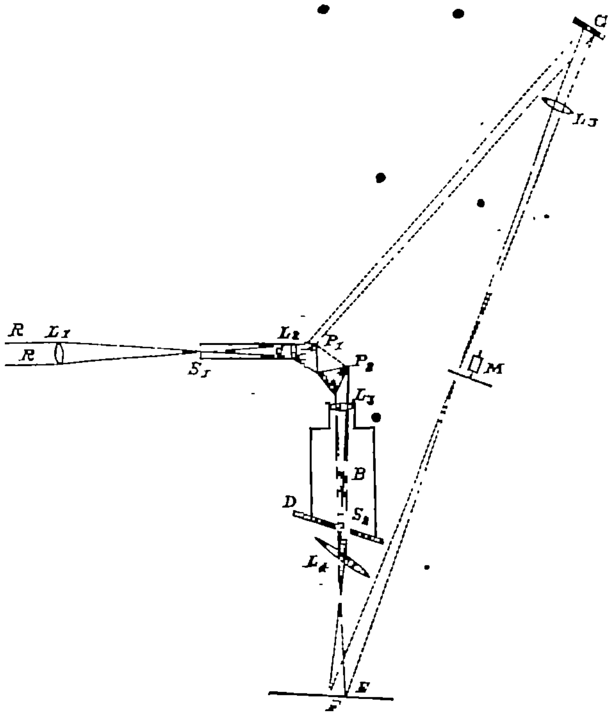

FIG. 1.—Colour Photometer.

Now, when we are working in the laboratory with a steady light, we may be at ease with this method, but when we come to working with light such as the sun, in which there may be constant variation owing to passing, and maybe usually imperceptible, mist, we are met with a difficulty; and in order to avoid this, General Festing and myself substituted another method, which I will now show you. We made the comparison light part of the light we were measuring. Light which enters the collimating lens partly passes through the prisms and is partly reflected from the first surface of the prism; that we utilise, thus giving a second shadow. The reflected rays from P_1 fall on G, a silver-on-glass mirror. They are collected by L_2, and form a white image of the prism also at F. The method we can adopt of altering the intensity of the comparison light is by means of rotating sectors, which can be opened or closed at will, and the two shadows thus made equally luminous. [Shown.] But although this is an excellent plan for some purposes, we have found it better to adopt a different method. You will recollect that the brightest part of the spectrum is in the yellow, and that it falls off in brightness on each side, so, instead of opening and closing the sectors, they are set at fixed intervals, and the slit is moved in front of the spectrum, just making the shadow cast by the reflected beam too dark or too light, and oscillating between the two till equality is discovered. The scale number is then noted, and the curve constructed as before. It must be remembered that, on each side of the yellow, equality can be established.

---

[1] Lecture delivered by Capt. W. de W. Abney, R.E., F.R.S., at the Royal Institution, on February 25, 1887.

This method of securing a comparison light is very much better for sun work than any other, as any variation in the light whose spectrum is to be measured affects the comparison light in the same degree. Thus, suppose I interpose an artificial cloud before the slit of the spectroscope, having adjusted the two shadows, it will be seen that the passage of steam in front of the slit does not alter the relative intensities; but this result must be received with caution. [The lecturer then proceeded to point out the contrast colours that the shadow of the rod illuminated by white light assumed.]

I must now make a digression. It must not be assumed that everyone has the same sense of colour, otherwise there would be no colour-blindness. Part of the researches of General Festing and myself have been on the subject of colour-blindness, and these I must briefly refer to. We test all who come by making them match the luminosity of colours with white light, as I have now shown you; and as a colour-blind person has only two fundamental colour-perceptions instead of three, his matching of luminosities is even more accurate than is that made by those whose eyes are normal or nearly normal. It is curious to note how many people are more or less deficient in colour-perception. Some have remarked that it is impossible that they were colour-blind, and would not believe it, and sometimes we have been staggered at first with the remarkable manner in which they recognised colour to which they ultimately proved deficient in perception. For instance, one gentleman when I asked him the name of a red colour patch, said it was sunset colour; he then named green and blue correctly, but when I reverted to the red patch he said green. On testing further he proved totally deficient in the colour-perception of red, and with a brilliant red patch he matched almost a black shadow. The diagram shows you the relative perceptions in the spectrum of this gentleman and myself. There are others who only see three-quarters, others half, and others a quarter the amount of red that we see, whilst some see none. Others see less green and others less violet, but I have met with no-one that can see more than myself or General Festing, whose colour-perceptions are almost identical. Hence we have called our curve of illumination the "normal curve."

We have tested several eminent artists in this manner, and about one-half of the number have been proved to see only three-quarters of the amount of red which we see. It might be thought that this would vitiate their powers of matching colour, but it is not so. They paint what they see, and although they see less red in a subject, they see the same deficiency in their pigments; hence they are correct. If totally deficient, the case of course would be different.

Let us carry our experiments a step further, and see what effect what is known as a turbid medium has upon the illuminating value of different parts of the spectrum. I have here water which has been rendered turbid in a very simple manner. In it has been very cautiously dropped an alcoholic solution of mastic. Now mastic is practically insoluble in water, and directly the alcoholic solution comes in contact with the water it separates out in very fine particles, which, from their very fineness, remain suspended in the water. I propose now to make an experiment with this turbid water.

I place a glass cell containing water in front of the slit, and on the screen I throw a patch of blue light. I now change it for turbid water in a cell This thickness much dims the blue; with a still greater thickness the blue has almost gone. If I measure the intensity of the light at each operation, I shall find that it diminishes according to a certain law, which is of the same nature as the law of absorption. For instance, if one inch diminishes the light one-half, the next will diminish it half of that again, the next half of that again, whilst the fourth inch will cause a final diminution of the total light of one-sixteenth. If the first inch allows only one-quarter of the light, the next will only allow one-sixteenth, and the fourth inch will only permit 1/256 part to pass. Let us, however, take a red patch of light and examine it in the same way. We shall find that, when the greater thickness of the turbid medium we used when examining the blue patch of light is placed in front of the slit, much more of this light is allowed to pass than of the blue. If we measure the light we shall find that the same law holds good as before, but that the proportion which passes is invariably greater with the red than the blue. The question then presents itself: Is there any connection between the amounts of the red and the blue which pass? Lord Rayleigh, some years ago, made a theoretical investigation of the subject; but, as far as I am aware, no definite experimental proof of the truth of the theory was made till it was tested last year by General Festing and myself. His law was that for any ray, and through the same thickness, the light transmitted varied inversely as the fourth power of the wave-length. The wave-length 6000 lies in the red, and the wave-length 4000 in the violet. Now 6000 is to 4000 as 3 to 2, and the fourth powers of these wave-lengths are as 81 to 16, or as about 5 to 1. If, then, the four inches of our turbid medium allowed three-quarters of this particular red ray to be transmitted, they would only allow $(\frac{3}{4})^5$, or rather less than one-fourth, of the blue ray to pass. Now this law is not like the law of absorption for ordinary absorbing media, such as coloured glass for instance, because here we have an increased loss of light running from the red to the blue, and it matters not how the medium is made turbid, whether by varnish, suspended sulphur, or what not. It holds in every case, so long as the particles which make the medium turbid are small enough; and please to recollect that it matters not in the least whether the medium which is rendered turbid is solid, liquid, or air. Sulphur is yellow in mass, and mastic varnish is nearly white, whilst tobacco-smoke when condensed is black, and very minute particles of water are colourless: it matters not what the colour is, the loss of light is *always* the same. The result is simply due to the scattering of light by fine particles, such particles being small in dimensions compared with a wave of light. Now, in this trough is suspended 1/1000 of a cubic inch of mastic varnish, and the water in it measures about 100 cubic inches, or is 100,000 times more in bulk than the varnish. Under a microscope of ordinary power it is impossible to distinguish any particles of varnish: it looks like a homogeneous fluid, though we know that mastic will not dissolve in water. Now a wave-length in the red is about 1/40,000 of an inch, and a little calculation will show that these particles are well within the necessary limits. Prof. Tyndall has delighted audiences here with an exposition of the effect of the scattering of light by small particles in the formation of artifical skies, and it would be superfluous for me to enter more into that. Suffice it to say that when particles are small enough to form the artificial blue sky they are fully small enough to obey the above law, and that even larger particles will suffice. We may sum up by saying that very fine particles scatter more blue light than red light, and that consequently more red light than blue light passes through a turbid medium, and that the rays obey the law prescribed by theory. I will exemplify this once more by using the whole spectrum and placing this cell, which contains hyposulphite of soda in solution in water, in front of the slit. By dropping in hydrochloric acid, the sulphur separates out in minute particles; and you will see that, as the particles increase in number, the violet, blue, green, and yellow disappear one by one and only red is left, and finally the red disappears itself.

Now let me revert to the question why the sun is red at sunset. Those who are lovers of landscape will have often seen on some bright summer's day that the most beautiful effects are those in which the distance is almost of a match to the sky. Distant hills, which when viewed close to are green or brown, when seen some five or ten miles away appear of a delicate and delicious, almost of a cobalt, blue colour. Now, what is the cause of this change in colour? It is simply that we have a sky formed between us and the distant ranges, the mere outline of which looms through it. The shadows are softened so as almost to leave no trace, and we have what artists call an atmospheric effect. If we go into another climate, such as Egypt or amongst the high Alps, we usually lose this effect. Distant mountains stand out crisp with black shadows, and the want of atmosphere is much felt. [Photographs showing these differences were shown.] Let us ask to what this is due. In such climates as England there is always a certain amount of moisture present in the atmosphere, and this moisture may be present as very minute particles of water—so minute indeed that they will not sink down in an atmosphere of normal density—or as vapour. When present as vapour the air is much more transparent, and it is a common expression to use, that when distant hills look "so close" rain may be expected shortly to follow, since the water is present in a state to precipitate in larger particles; but when present as small particles of water the hills look very distant, owing to what we may call the haze between us and them. In recent weeks everyone has been able to see very multiplied effects of such haze. The ends of long streets, for instance, have been scarcely visible though the sun may have been shining, and at night the long vistas of gas lamps have shown light having an increasing redness as they became more distant. Everyone admits the presence of mist on these occasions, and this mist must be merely a collection of intangible and very minute particles of suspended water. In a distant landscape we have simply the same or a smaller quantity of street-mist occupying, instead of perhaps 1000 yards, ten times that distance. Now I would ask, What effect would such a mist have upon the light of the sun which shone through it?

It is not in the bounds of present possibility to get outside our atmosphere and measure by the plan I have described to you the different illuminating values of the different rays, but this we can do:—First, we can measure these values at different altitudes of the sun, and this means measuring the effect on each ray after passing through different thicknesses of the atmosphere, either at different times of day, or at different times of the year, about the same hour. Second, by taking the instrument up to some such elevation as that to which Langley took his bolometer at Mount Whitney, and so to leave the densest part of the atmosphere below us. Now, I have adopted both these plans. For more than a year I have taken measurements of sunlight in my laboratory at South Kensington, and I have also taken the instrument up to 8000 feet high in the Alps, and made observations *there*, and with a result which is satisfactory in that both sets of observations show that the law which holds with artificially turbid media is under ordinary circumstances obeyed by sunlight in passing through our air: which is, you will remember, that more of the red is transmitted than of the violet, the amount of each depending on the wave-length. The luminosity of the spectrum observed at the Riffel I have used as my standard luminosity, and compared all others with it. The result for four days you see in the diagram.

I have diagrammatically shown the amount of different colours which penetrated on the same days, taking the Riffel as ten. It will be seen that on December 23 we have really very little violet and less than half the green, although we have four-fifths of the red.

The next diagram before you shows the minimum loss of light which I have observed for different air thicknesses. On the top we have the calculated intensities of the different rays outside our atmosphere. Thus we have that through one atmosphere, and two, three, and four; and you will see what enormous absorption there is in the blue end at four atmospheres. The areas of these curves, which give the total luminosity of the light, are 761, 662, 577, 503, and 439; and if observed as astronomers observe the absorption of light, by means of stellar observations, they would have had the values, 761, 664, 578, 504, and 439—a very close approximation one to the other.

Next notice in the diagram that the top of the curve gradually inclines to go to the red end of the spectrum as you get the light transmitted through more and more air, and I should like to show you that this is the case in a laboratory experiment. Taking a slide with a wide and long slot in it, a portion is occupied by a right-angled prism, one of the angles of 45° being towards the centre of the slot. By sliding this prism in front of the spectrum I can deflect outwards any portion of the spectrum I like, and by a mirror can reflect it through a second lens, forming a patch of light on the screen overlapping the patch of light formed by the undeflected rays. If the two patches be exactly equal, white light is formed. Now, by placing a rod as before in front of the patch, I have two coloured stripes in a white field, and though the background remains of the same intensity of white, the intensities of the two stripes can be altered by moving the right-angled prism through the spectrum. The two stripes are now apparently equally luminous, and I see the point of equality is where the edge of the right-angled prism is in the green Placing a narrow cell filled with our turbid medium in front of the slit, I find that the equality is disturbed, and I have to allow more of the yellow to come into the patch formed by the blue end of the spectrum, and consequently less of it in the red end. I again establish equality. Placing a thicker cell in front, equality is again disturbed, and I have to have less yellow still in the red half, and more in the blue half. I now remove the cell, and the inequality of luminosity is still more glaring. This shows, then, that the rays of maximum luminosity must travel towards the red as the thickness of the turbid medium is increased.

The observations at 8000 feet, here recorded, were taken on September 15 at noon, and of course in latitude 46° the sun could not be overhead, but had to traverse what would be almost exactly equivalent to the atmosphere at sea-level. It is much nearer the calculated intensity for no atmosphere intervening, than it is for one atmosphere. The explanation of this is easy. The air is denser at sea-level than at 8000 feet up, and the lower stratum is more likely to hold small water particles or dust in suspension than is the higher.

FIG. 2.—Relative Luminosities.

For, however small the particles may be, they will have a greater tendency to sink in a rare air than in a denser one, and less water vapour can be held per cubic foot. Looking, then, from my laboratory at South Kensington, we have to look through a proportionately larger quantity of suspended particles than we have at a high altitude when the air thicknesses are the same; and consequently the absorption is proportionately greater at sea-level that at 8000 feet high. This leads us to the fact that the real intensity of illumination of the different rays outside the atmosphere is greater than it is calculated from observations near sea-level. Prof. Langley, in this theatre, in a remarkable and interesting lecture, in which he described his journey up Mount Whitney to about 12,000 feet, told us that the sun was really blue

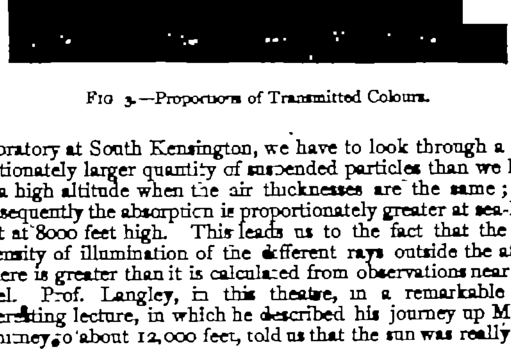

FIG 3.—Proportions of Transmitted Colours.

outside our atmosphere, and at first blush the amount of extra blue which he deduced to be present in it would, he thought, make it so; but though he surmised the result from experiments made with rotating disks of coloured paper, he did not, I think, try the method of using pure colours, and consequently, I believe, slightly exaggerated the blueness which would result. I have taken Prof. Langley's calculations of the increase of intensity for the different rays, which I may say do not quite agree with mine, and I have prepared a mask which I can place in the spectrum giving the different proportions of each ray as calculated by him, and this when placed in front of the spectrum will show you that the real colour of sunlight outside the atmosphere, as calculated by Langley, can scarcely be called bluish. Alongside I place a patch of light which is very closely the colour of sunlight on a July day at noon in England. This comparison will enable you to gauge the blueness, and you will see that it is not very blue, and, in fact, not bluer perceptibly than that we have at the Riffel, the colour of the sunlight at which place I show in a similar way. I have also prepared some screens to show you the value of sunlight after passing through five and ten atmospheres. On an ordinary clear day you will see what a yellowness there is in the colour. It seems that after a certain amount of blue is present in white light the addition of more makes but little difference in the tint. But these last patches show that the light which passes through the atmosphere when it is feebly charged with particles does not induce the red of the sun as seen through a fog. It only requires more suspended particles in any thickness to induce it.

In observations made at the Riffel, and at 14,000 feet, I have found that it is possible to see far into the ultra-violet, and to distinguish and measure lines in the sun's spectrum which can ordinarily only be seen by the aid of a fluorescent eye-piece or by means of photography. Circumstantial evidence tends to show that the burning of the skin, which always takes place in these high altitudes in sunlight, is due to the great increase in the ultra-violet rays. It may be remarked that the same kind of burning is effected by the electric arc light, which is known to be very rich in these rays.

Again, to use a homely phrase, "You cannot eat your cake and have it." You cannot have a large quantity of blue rays present in your direct sunlight, and have a luminous blue sky. The latter must always be light scattered from the former. Now, in the high Alps you have, on a clear day, a deep blue-black sky, very different indeed from the blue sky of Italy or of England; and as it is the sky which is the chief agent in lighting up the shadows, not only in those regions do we have dark shadows on account of no intervening—what I will call—mist, but because the sky itself is so little luminous. In an artistic point of view this is important. The warmth of an English landscape in sunlight is due to the highest lights being yellowish, and to the shadows being bluish from the sky-light illuminating them. In the high Alps the high lights are colder, being bluer, and the shadows are dark, and chiefly illuminated by reflected direct sunlight. Those who have travelled abroad will know what the effect is. A painting in the Alps, at any high elevation, is rarely pleasing, although it may be true to Nature. It looks cold, and somewhat harsh and blue.

In London we are often favoured with easterly winds, and these, unpleasant in other ways, are also destructive of that portion of the sunlight which is the most chemically active on living organisms. The sunlight composition of a July day may, by the prevalence of an easterly wind, be reduced to that of a November day, as I have proved by actual measurement. In this case it is not the water particles which act as scatterers, but the carbon particles from the smoke.

Knowing, then, the cause of the change in the colour of sunlight, we can make an artificial sunset, in which we have an imitation light passing through increasing thicknesses of air largely charged with water particles. [The image of a circular diaphragm placed in front of the electric light was thrown on the screen in imitation of the sun, and a cell containing hyposulphite of soda placed in the beam. Hydrochloric acid was then added: as the fine particles of sulphur were formed, the disk of light assumed a yellow tint, and as the decomposition of the hyposulphite progressed, it assumed an orange and finally a deep red tint.] With this experiment I terminate my lecture, hoping that in some degree I have answered the question I propounded at the outset: why the sun is red when seen through a fog.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—From the University accounts for 1886, just issued, we learn that the Mathematical Tripos Examiners are paid 348*l.*; Examiners in Natural Science, 575*l.*; in Medicine and Surgery, 210*l.*; all extremely moderate payments.

Science Professors received 3725*l.* from the University Chest, 1800*l.* from the Common University Fund (derived from tax on the Colleges), besides payments from special endowments; Readers, Demonstrators, and other officers connected with Science and Medicine, 2100*l.* from the University Chest; 1800*l.* from the Common University Fund. Total, 9425*l.* for teachers mainly.

The University Observatory cost 786*l.*, in addition to 164*l.* from the Sheepshanks Fund. The Botanic Garden cost 1223*l.*; the Museums and Lecture Rooms, 4221*l.*, including 100*l.* for Dr. Guillemard's collection of bird-skins from the voyage of the *Marchesa*, 11*l.* for bird-skins bought by Prof. Newton at the Jardine sale, and 8*l.* 10*s.* for a skeleton of a European elk. The Pathological Laboratory cost 167*l.* out of the foregoing amount; the Department of Human Anatomy, 356*l.*; the Woodwardian Museum, 498*l.*; the Chemical Laboratory, 517*l.*; the Cavendish Laboratory, 274*l.*, including 60*l.* for instruments. The new dissecting-room (iron) for Human Anatomy cost 350*l.*, an additional class-room for Physiology 10*l.*, charged to the Museums Reserve Fund.

At Gonville and Caius College, Dr. Shuttleworth's Scholarship of 60*l.* for three years, open to medical students of the University of not less than eight terms' standing, given for proficiency in Botany and Comparative Anatomy, has been awarded to Francis Henry Edgeworth, B.A., Scholar of the College.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, March 3.—"On the Limiting Distance of Speech by Telephone." By William Henry Preece, F.R.S.

The law that determines the distance to which speaking by telephone on land-lines is possible, is just the same as that which determines the number of currents which can be transmitted through a submarine cable in a second.

It is dependent on a time-constant varying with the conditions of the circuit, invariable for the same uniform circuit, but differing for different circuits. It represents the time that elapses from the instant contact is made at the sending-end to the instant that the current begins to appear at the receiving-end. It is given by the following equation:—

$$a = \mathrm{B}krl^2,$$

B being a constant dependent principally on the units used; k the inductive capacity per unit length (mile or knot); r the resistance per unit length, and l the lengths in miles or knots.

The number of reversals which can be produced at the end of a wire per second is quite independent of the impressed E.M.F., and therefore of the strength of the current. But it depends upon the sensitiveness of the apparatus used to receive the currents. This is why such discordant results are obtained by different observers who attempt to measure the velocity of currents of electricity. It is also why the telephone is such an admirable instrument for research—for it is sensitive to the least increment or decrement of current.

The inductive capacity of overhead and underground wires was measured with great care on very dry days in different parts of the country.

The results come out as follows:—

	Capacity per mile, microfarads		Resistance per mile, B.A. ohms
No. 7½ iron wire	0·0168	...	12·0
No. 12½ copper wire	0·0124	...	5·7
Gutta-percha-covered wire in iron pipes	0·2500	...	23·0
Gutta-percha-covered wire in cables	0·2900	...	10·25

It then became necessary to determine the speed of the current through wires of different lengths, resistances, and capacities.

It was found that, for mixed wires, the speed was given by the equation

$$t = 32 \times 10^{-8}\,\mathrm{KR},$$

but for copper alone the constant was 22×10^{-8}.

The limiting distance through which it is possible to speak varies inversely with the speed of the current, and that the speed of the current varies inversely with the product of the total resistance and the total capacity of the circuit. Hence the number of reversals that it is possible to send through any circuit varies inversely with the product of the total resistance (R) and the total capacity (K), or the limiting distance—

$$S = KR \times \text{constant} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

This is only another form of Thomson's law for $K = lk$, and $R = kr$, and

$$\therefore S = krl^2 \times \text{constant}.$$

If the equation (1) be put into this form,

$$A = krx^2, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

and A be given the following values:—

Copper (overhead)	15,000
Cables and underground	12,000
Iron (overhead	10,000

the limiting distance (x) through which speech is possible is

$$x^2 = A/kr.$$

There is an interesting consequence of Thomson's law which comes out of these experiments, and that is whether the line be a single wire completed by the earth, or a double wire making a metallic circuit, the rate of speed between the two ends is exactly the same, and therefore the distance we can speak through is just the same whether we use a single or double wire circuit. This is owing to the fact that though in the latter case we double the total resistance, we halve the total capacity, and therefore the product remains the same.

The difference between copper and iron is clearly due to self-induction, or to the electro-magnetic inertia of the latter, and the difference between copper overground and copper underground is due to the facility that the leakage of insulators offers to the rapid discharge to earth, at innumerable points, of the static charge, which in gutta-percha-covered wire can find an exit only at the ends.

It is also evident that there is no difficulty in working telephones through underground wires, even though they attain fifty miles in length, and in fact it would be better to work underground with proper copper wire from London to Brighton, than to use iron wires along the railway telegraph poles, owing to the absence of external disturbances in the former case.

March 17.—"Second Note on the Geometrical Construction of the Cell of the Honey Bee (Roy. Soc. Proc. vol. xxxix. p. 253, and vol. xli. p. 442)." By Prof. H. Hennessy, F.R.S.

The author deduces from the results established in his communications as above cited that, while the trihedral pyramid at the apex of the cell may be inscribed in a sphere whose diameter, D, is equal to the sum of the three edges of the pyramid, another sphere may be inscribed within the cell touching all of its nine faces and whose diameter, D', is equal to the diameter of the cell, and that between these diameters the following relation exists:—

$$\frac{D}{D'} = \left(\frac{3}{2}\right)^{\frac{1}{2}}.$$

The connexion between the geometrical cell and its inscribed and circumscribing spheres is pointed out as possibly bearing on the mode of formation of the actual cells.

"A Coal-dust Explosion." By W. Galloway. Communicated by R. H. Scott, M.A., F.R.S.

Zoological Society, March 1.—Prof. W. H. Flower, F.R.S., President, in the chair.—Prof. Jeffrey Bell read extracts from a communication sent to him by Mr. Edgar Thurston, Superintendent of the Government Central Museum, Madras, containing observations on two species of Batrachians of the genus *Cacopus*.—Mr. O. Salvin (on behalf of Mr. F. D. Godman) exhibited a pair of a large and rare Butterfly (*Ornithoptera victoriæ*), the male of which had been hitherto undescribed. These specimens were obtained at the end of May 1886 by Mr. C. M. Woodford, at North-West Bay, Maleita Island, one of the Solomon group.—Mr. E. B. Poulton read a paper containing an account of his experiments on the protective value of colour and markings in insects (especially in Lepidopterous larvæ) in their relation to Vertebrata. It was found that conspicuous insects were nearly always refused by birds and lizards, but that they were eaten in extreme hunger: hence the unpleasant taste failed as a protection under these circumstances. Further, conspicuous and unpalatable insects, although widely separated, tended to converge in colour and pattern, being thus more easily seen and remembered by their enemies. In the insects protected by resembling their surroundings it was observed that mere size might prevent the attacks of small enemies. Some such insects were unpalatable, but could not be distinguished from the others. In tracing the inedibility through the stages, it was found that no inedible imago was edible in the larval stage; in this stage therefore the unpleasant taste arose.—Mr. G. A. Boulenger read a paper descriptive of the fishes collected by the late Mr. Clarence Buckley in Ecuador. The set of all the species in the collection acquired by the British Museum in 1880 contained a large number of highly interesting and well-preserved specimens. Amongst them were representatives of ten species described as new to science.—Mr. Richard S. Wray, read a note on a vestigial structure in the adult Ostrich representing the distal phalanges of the third digit.—Mr. John H. Ponsonby communicated (on behalf of Mr. Andrew Garrett) the second and concluding part of a paper on the Terrestrial Mollusks of the Viti or Fiji Islands.—Mr. Edgar A. Smith gave an account of a small collection of shells from the Loo-Choo Islands, made by Mr. H. Pryer.

Geological Society, February 18.—Annual General Meeting.—Prof. J. W. Judd, F.R.S., President, in the chair.—Having presented the various medals, and the proceeds of the Donation Funds in the gift of the Society, the President read his Anniversary Address, which we have already printed.—The ballot for the Council and Officers was taken, and the following were duly elected for the ensuing year:—President: Prof. J. W. Judd, F.R.S. Vice-Presidents: H. Bauerman, Prof. T. G. Bonney, F.R.S., A. Geikie, F.R.S., Henry Woodward, F.R.S. Secretaries: W. T. Blanford, F.R.S., and W. H. Hudleston, F.R.S. Foreign Secretary: Warington W. Smyth, F.R.S. Treasurer: Prof. T. Wiltshire. Council: H. Bauerman, W. T. Blanford, F.R.S., Prof. T. G. Bonney, F.R.S., A. Champernowne, Thomas Davies, Prof. P. M. Duncan, F.R.S., A. Geikie, F.R.S., Henry Hicks, F.R.S., Rev. Edwin Hill, W. H. Hudleston, F.R.S., J. W. Hulke, F.R.S., Prof. T. McKenny Hughes, Prof. T. Rupert Jones, F.R.S., Prof. J. W. Judd, F.R.S., R. Lydekker, J. E. Marr, E. T. Newton, Prof. H. G. Seeley, F.R.S., Warington W. Smyth, F.R.S., J. J. H. Teall, Prof. T. Wiltshire, Rev. H. H. Winwood, Henry Woodward, F.R.S.

February 23.—Prof. J. W. Judd, F.R.S., President, in the chair.—The following communications were read:—On the origin of dry chalk valleys and of Coombe rock, by Mr. Clement Reid. Whilst engaged in examining the Pleistocene deposits of Sussex, for the Geological Survey, the author observed that the Coombe rock differs from anything commonly seen in the strongly glaciated districts of the Yorkshire and Lincolnshire Wolds. As in these localities, the seaward slope of the South Downs is broken by the line of a partially buried sea-cliff before passing under the low-lying drift areas. Subsequent to the formation of this sea-cliff a mass of angular flint and chalk detritus spread out from the Downs over the low lands, being seldom found far up the valleys. This is the Coombe rock, which passes further on into a worthless mixture of angular flint and loam, and at a still greater distance into almost clean brick-earth. It is not of glacial origin, neither is it marine, nor is it a gravel formed by ordinary fluviatile action. The rolling outline of the Downs, and the steep-sided dry valleys point to conditions which have passed away. However much rain may fall, the upper parts of these valleys are always dry, and no running water can be found where the incline of the bottom of the valley exceeds the slope of the plane of saturation—never more than 60 feet per mile. The author discussed the various explanations which have been offered. In suggesting an origin for the dry valleys and Coombe rock, he considers that the fauna and flora, both at Fisherton and Bovey Tracey, point to a great degree of cold, from 20° to 30° lower than what now prevails in the South of England. The ground would thus be frozen to the depth of several hundred feet, and the drainage system of the chalk entirely modified. There would be no underground circulation. The summer rains would immediately run off any steep slope, often in violent torrents. These would tear up the layer of rubble already loosened by the frost, carrying down masses of unthawed chalk too rapidly for solvents to have much effect. No Coombe rock is found in valleys that have a greater slope than 100 feet per mile. There is no need of excessive rainfall; it might have been a dry period corresponding to that of the loess. If the time had not been short, all soft rocks in the South of England would have been planed down to one gently undulating surface like the plains of Russia and Siberia. Such tundra-conditions may have occurred more than once.—Probable amount of former glaciation of Norway, as demonstrated by the present condition of rocks upon and near the western coast, by Mr. W. F. Stanley.

Mathematical Society, March 10.—Sir James Cockle, F.R.S., President, in the chair.—The following communications were made:—A metrical property of plane curves, by R. Lachlan.—Note on the Weierstrass functions, by Mr. A. G. Greenhill.—Second paper on the change of the independent variable; with applications to some functions of the reciprocant kind, by C. Leudesdorf.—A note on knots, by Mr. A. B. Kempe, F.R.S.

Chemical Society, March 3.—Dr. Hugo Muller, F.R.S., President, in the chair.—The following papers were read:—Tartaric and racemic acids and the magnetic rotatory power of their ethyl salts, by Dr. W. H. Perkin, F.R.S.—Anhydracetonebenzil, by Mr. Francis R. Japp, F.R.S., and Mr. Cosmo Innes Burton.—Condensation compounds of benzil with ketones, by the same.—Constitution of glycosine, by Mr. Francis R. Japp, F.R.S., and Mr. E. Cleminshaw.—Diphenylglyoxaline and methyldiphenylglyoxaline, by Mr. Francis R. Japp, F.R.S.—Dehydracetic acid, by Dr. W. H. Perkin, Jun.—The colouring-matter of *Drosera Whittakeri*, by Prof. E. H. Rennie.—Further notes on the di-haloid derivatives of thiocarbamide, by Dr. George McGowan.

Anthropological Institute, March 8.—Mr. Francis Galton, F.R.S., President, in the chair.—Mr. A. L. Lewis read a paper on stone circles near Aberdeen. In this paper Mr. Lewis described in detail two circles near Dyce and Portlethen respectively, and drew particular attention to the fact that they differ in two important particulars from the circles of Southern Britain. In former papers on stone circles the author had insisted on the presence of a special reference to the north-east, but in these circles the main direction is north and south. They are further distinguished from the southern circles by the existence of an oblong stone flanked by two upright stones, which is indeed their principal feature, and which exists nowhere except in the Aberdeen district, where it is almost universal. Mr. Lewis regarded the Aberdeen circles as having more affinity to the "giants' graves" found in the north of Ireland, than to the English circles to which it has always been sought to ally them.—The following papers were also read:—Palæolithic implements from the drift-gravels of the Singrauli Basin, South Mirzapore, by Mr. J. Cockburn.—Stone implements from Perak, by Mr. Abraham Hale.

Entomological Society, March 2.—Dr. D. Sharp, President, in the chair.—Mr. Slater exhibited, with the object of showing the effect of food in causing variation in Lepidoptera, two specimens of *Arctia caja*, one of which was bred from a larva fed on lime-leaves, and the other from a larva fed on low plants, the ordinary pabulum of the species.—Capt. H. J. Elwes exhibited a large number of Lepidoptera-Heterocera, caught by him at Darjeeling, in Sikkim, at an elevation of 7000 feet, on the night of August 4, 1886, between 9 p.m. and 1 a.m. The specimens exhibited represented upwards of 120 species, belonging to Bombyces, Noctuæ, Geometræ, Crambidæ, &c., many of which were believed to be undescribed. Capt. Elwes stated that Mr. A. R. Wallace's observations on the conditions most favourable for collecting moths in the tropics were fully confirmed by his own experience during four months' collecting in Sikkim and the Khasias. The conditions referred to were a dark wet night in the rainy season; a situation commanding a large extent of virgin forest and uncultivated ground; and a whitewashed veranda with powerful lamps in it. He also made some remarks on the Khasia Hills, the southern slopes of which he believed to be the true habitat of the greater part of those insects described many years ago by Prof. Westwood and others as coming from Sylhet. A discussion ensued, in which Mr. McLachlan, Dr. Sharp, Mr. Champion, Mr. Kirby, and others took part.—The Rev. W. W. Fowler exhibited a specimen of *Cathormiocerus socius*, taken at Sandown, Isle of Wight.—Mr. S. Stevens exhibited specimens of *Cathormiocerus maritimus* and *Platytarsus hirtus*.—Mr. F. Grut said he was requested by M. Péringuey, of Cape Town, to announce that the latter was engaged on a monograph of the genus *Hipporrhinus*, and that he would be glad to receive specimens and other assistance from British entomologists.—Mr. Gervase F. Mathew, R.N., communicated a paper entitled "Descriptions of new species of Rhopalocera from the Solomon Islands."—Mr. G. T. Baker communicated the following papers: "Description of a new species of the Lepidopterous genus *Carama*, together with a few notes on the genus"; and "Description of a new genus of Rhopalocera allied to *Thecla*."

Institution of Civil Engineers, February 22.—Mr. Edward Woods, President, in the chair.—A paper was read on irrigation in Lower Egypt, by Mr. William Willcocks.

March 1.—Mr. Edward Woods, President, in the chair.—A paper was read on dredging-operations and appliances, by Mr. John James Webster. The author described the objects for which dredging-operations are generally carried out, and spoke of the advantage of obtaining the aid of natural scour, when possible, for supplementing or dispensing with dredging. The various kinds of appliances used were fully described.

March 15.—Mr. Edward Woods, President, in the chair.—A paper was read on the treatment of gun-steel, by Colonel Eardly Maitland, R.A.

PARIS

Academy of Sciences, March 14.—M. Janssen, President, in the chair.—Reply to M. Houzeau's additional note, by M. Lœwy. It is argued that M. Houzeau's mistake lies in the arrangement proposed by him in 1871, which is practically that of a sextant with fixed opening. The principle of the sextant is based on the combination of two mirrors, which in virtue of known optical conditions must give it an undoubted superiority over M. Houzeau's apparatus, which is provided with only one mirror.—On a problem relating to the theory of minima surfaces, by M. Gaston Darboux. To the different solutions of the problem given in vol. cii. of the *Comptes rendus* (1886), is here added another which rests on a new genesis of minima surfaces proposed in an important memoir by M. Ribaucour.—On the great movements of the atmosphere, and on M. Colladon's note of March 7, by M. H. Faye. The paper deals with M. Colladon's suggestion, based on M. Weyher's recent experiments, that rotatory movements with vertical axis may have both an ascending and a descending direction, thus presenting a middle term between the extreme views of M. Faye and his opponents.—On the artificial production of the ruby, by M. Fremy. Some remarks are presented on the two processes elaborated by MM. Fremy and Feil, in connexion with the recent death of M. Feil. A third method is referred to which has since been brought to great perfection with the co-operation of M. Verneuil. A paper followed, by MM. Fremy and Verneuil, on the action of the fluorides on alumina in connexion with the same subject.—The small *Ursus spelæus* of Gargas, by M. Albert Gaudry. A description is given of this species of cave-bear, a skeleton of which, made up with the bones of several individuals, has just been mounted in the new room for palæontological specimens in the Natural History Museum.—Details collected from various sources on the earthquake of February 23, by M. F. Fouqué. An account is given of the vibrations recorded at the Observatories of Lisbon, Wilhelmshafen, and Seville; the general conclusion being that the magnetic disturbances were not the cause, but rather the effect, of the shocks.—Report on MM. Guyou and Simart's memoir on the development of naval geometry as applied to the question of the stability of vessels, by the Commissioners, MM. Phillips, Lévy, Sarrau, and de Jonquières. The report speaks favourably of MM. Guyou and Simart's studies, which greatly reduce the elaborate calculations hitherto required to be worked out in determining questions of stability from the theoretical and practical stand-points.—Experiments on the effects of the transfusion of blood into the heads of decapitated animals (second note), by MM. G. Hayem and G. Barrier. The experiments show that the time is limited to about ten seconds, during which it is possible by transfusion of arterial blood to momentarily revive the action of the sensor and motor cortical centres.—On a correlation between earthquakes and the declinations of the moon, by M. H. de Parville. A systematic study of lunar and terrestial phenomena continued for a quarter of a century leads the author to infer a distinct relation between lunar declination and earthquakes, the general law being that the disturbances occur either at the equilune, the lunistice, or exactly when the sun and moon have the same declination.—On the variations in the absorption-spectra of didymium, by M. Henri Becquerel. Fresh experiments here described confirm the previous conclusion of the author regarding the presence of foreign substances in didymium, as revealed by its absorption-spectra. Some of these bodies may possibly be diverse combinations of the same with another substance or with itself, such combinations being so stable that it has hitherto been impossible to transform one into the other. —On the specific heat of a salt-solution, by M. P. Duhem. The method employed by the author to find the expression of the heat of solution is here shown to lead also to the expression of the specific heat of a salt-solution.—On a standard-pile, by M. Gouy. The author describes a convenient standard of electromotor force, formed with zinc, sulphate of zinc, mercury, and dioxide of mercury.—Researches on the application of rotatory force to the study of certain compounds produced in the solutions of tartaric acid, by M. D. Gernez.—On a general method of forming the manganites from the permanganates, by M. G. Rousseau. The metallic permanganates are transformed to manganites at a temperature ranging from 100° to 150° C., and as the law of decomposition here formulated is applicable to the compounds of the whole series, it is proposed as a general method for obtaining most of the metallic manganates.—On the reticulated structure of the protoplasm of the Infusoria, by M. Fabre-Domergue.

BERLIN

Physiological Society, February 25.—Prof. Munk in the chair.—The President communicated two treatises sent, for publication in the Proceedings of the Society, by Prof. Kronecker, of Berne. In the first, Prof. Kronecker had, in conjunction with Fräulein Popoff, examined the formation of serous albumen in the intestinal canal. As reagents they made use of the hearts of frogs and tortoises, void of blood, which were stimulated to contraction only when blood or a solution of serous albumen was poured through them, but under every other albuminous or saline solution remained inactive. Stomachic peptone was incapable of nourishing the heart. When, however, the peptone was kept for some time in the stomach or in an intestinal coil connected with the mesentery, then it acted on the heart in the same way as did serous albumen. Pancreatic peptone was incapable, either of itself or after remaining in the stomach or the intestine, of stimulating the heart to contraction; by exposure for a considerable time to the air, the peptone likewise became nutritious to the heart.—In the second treatise, containing an investigation by Prof. Kronecker and Fräulein Rink, it was demonstrated that in peptone solution two kinds of Bacteria are developed in the presence of air: *Bacillus restituens*, which transformed the peptone into serous albumen, exactly in the same way as did the living mucous membrane of the stomach; and *Bacillus virescens*, which liquefied the alimentary gelatine and imparted a deep blue colouring to all sterilised substrata when exposed to the air. This latter Bacillus operated poisonously on the heart. —Dr. Benda spoke of the function of the cross-striped muscle substance. By anatomical investigation of the muscles of the river crayfish he had arrived at the conviction that it was only the cross-striped substance which generated the contraction, while it was in the highest degree probable that the protoplasm discharged the office of mediation between the ends of the motory nerves and the contractile substance.—Prof. Ewald described some comparative experiments performed on three patients to ascertain the amount of nourishment with different commercial peptones, with eggs, and with eggs to which were added pepsine and hydrate of chlorine. The nutritive fluids were supplied *per enema*, and the individually very changeable nitrogenous transpositions were determined by careful analyses of the ingesta and egesta.

Meteorological Society, March 1.—Prof. von Bezold in the chair.—Dr. Kremser communicated the results of an investigation into the variability of atmospheric temperature in Germany. Variability he understood, in accordance with Hann's definition, to be the difference between the mean temperature on two consecutive days. Such variability was found by Dr. Kremser to attain its greatest magnitude in the mountains and in the eastern provinces, and its least range along the coasts of the Baltic and North sea, and on the islands. The maximum was in the Riesengebirge, 4°·3 F., the minimum on the islands of the North Sea, 2°·3. If the monthly means were arranged in chronological sequence for the year, there was presented an annual march of temperature with a chief maximum in December and a secondary in June. The variability of temperature at each of the different hours, 6 a.m., 2 p.m., and 10 p.m., yielded values differing from those of the variability of the daily means of temperature. Yet the yearly march of variability of each of the different hours already specified was similar to the yearly march of variability of the daily means. The greatest change of temperature affecting an individual period of twenty-four hours was observed in Clausen, amounting to 68° F. In Berlin, the greatest change to which the same period was liable was 24°·7; in Munich it was 30°·6. A variability of 18°·0 affecting a period of twenty-four hours might be expected in the course of a year in the east and south, but along the North Sea coast only in a period of three years. As the basis for the above conclusions, Dr. Kremser had made use of the observations of ten years.

BOOKS, PAMPHLETS, and SERIALS RECEIVED

Gairloch: J. H. Dixon (Edinburgh).—Catalogue of Siwalik Vertebrata contained in the Geological Department of the Indian Museum, Calcutta; part 1, Mammalia; part 2, Aves, Reptilia, and Pisces: R. Lydekker (Calcutta).—Catalogue of Pleistocene and Prehistoric Vertebrata contained in the Geological Department of the Indian Museum, Calcutta: R. Lydekker (Calcutta).—Memoirs of the Geological Survey of India, Palæontologia Indica, ser. xiii. Salt Range Fossils: W. Waagen; ser. xii. The Fossil Flora of the Gondwana System, vol. iv. part 2, The Fossil Flora of some of the Coal-Fields in Western Bengal: O. Feistmantel (Trübner).—*Challenger* Reports, vol. xviii. 3 parts.—Science of Thought: F. Max Müller (Longmans).—Le Commozioni Telluriche il Terremoto del 23 Febbraio, 1887 (Roux, Torino).—On Over-work and Premature Mental Decay, 4th edition: C. H. F. THURSDAY, MARCH 31, 1887

A UNIVERSITY FOR LONDON

WE have from time to time informed our readers of the progress made in the attempt to organise the capacities for teaching and learning in London into a more complete and more efficient shape. The movement is most natural and admirable. What we have desired is to warn those interested in it not to lose sight of the full result obtainable while busied in their attempts to remove a particular grievance or further a particular interest. Each constituent of the future University—the Colleges and professional schools, the teachers and the students, the medical corporations, and the Senate and Convocation of the existing University of London—each is indispensable. Any one of these can block the way for the rest. Together they make up amply sufficient elements for the foundation desired, and this foundation would not be strengthened, but weakened, by attempts (which can never be realised) to bring in such heterogeneous elements as the British Museum or the Royal Society, the Government technical schools or the Corporation of the City and its Companies.

The present state of affairs is, we believe, pretty much as follows. The Convocation of the present University, in which the first efforts towards its reform began some six or seven years ago, rejected a scheme presented to it by a Committee of forty of its most distinguished members, of which Lord Justice Fry was the chairman. Among them were the present Home Secretary, the President of the Royal College of Surgeons, Mr. Justice Wills, Sir Joseph Lister, Dr. Wilks, Prof. Michael Foster, Dr. Bristowe, Mr. Power, Mr. Howse, Dr. Ord, Prof. Unwin, Mr. Thiselton Dyer, Mr. Anstie, Prof. Carey Foster, the Rev. Dr. Dale, and Mr. Cozens-Hardy. A second and much smaller Committee was then constructed by Mr. (now Sir Philip) Magnus, who had taken the lead in opposing some of the provisions of the previous scheme, and this Committee brought up, on report, a second and modified plan of reform, which passed Convocation last May, not without opposition, but by substantial majorities and with only minor alterations. This second Committee laid the amended scheme before the Senate and remain in charge of it. Meantime the Senate had appointed a Committee of its own members, who have for several months been elaborating a scheme of their own, who have already conferred both with the Committee of Convocation and with one appointed by the Teaching University Association, and who have now presented their Report to the Senate. Some opportune vacancies, which occurred in the latter body during the last two or three years, have led to the presence of Lord Justice Fry himself, and of Dr. Wilks, Dr. Pye Smith, and Prof. Carey Foster. It seems probable that a scheme of reform will be accepted both by Senate and Convocation, which will go as far as most who are sanguine could expect, and farther than most who are timid will approve. The Convocation of graduates will gain more direct representation, and the teachers of the Colleges which send up men for the University degrees will probably be also directly represented on the Senate. But a more important improvement, one that would be useful even if the Senate were to remain exactly as it is, will almost certainly be the institution of Boards of Studies, which will represent the teachers and probably the examiners in each Faculty, much like the standing Committees which sit under the same name at Oxford. The general body of teachers which would elect these Boards would include provincial as well as London Professors, and would more or less correspond to the Congregation of Oxford, but it would probably seldom meet, except for the purpose of election of the representative Boards of Studies.

The Association for Promoting a Teaching University held a general meeting several weeks ago, and admirable speeches were made, especially those of Mr. Marshall and Mr. Bryce, but it lacked the enthusiasm given by numbers. After communicating with the principal London Colleges and Medical Schools, the Council of the Association propose to apply either to the Crown or to Parliament, probably with the object of securing a Royal Commission on the whole question.

University College, after coquetting with the Victoria University (which has apparently not welcomed with great warmth the proposal of accepting so large and distant a Society as its daughter), is now engaged in direct negotiations with King's College, with a view to agreement upon a common plan of action. This is a prudent course, for if the reform of the University of London should prove unattainable or inadequate, the two chief Colleges, by acting together, would be far more likely to obtain the privileges which they then would rightly seek.

Meantime the great medical corporations have become tired of waiting. They represent the most urgent grievance, and are fully justified in pressing for its redress. They appear likely to ask for power to grant degrees to their own licentiates, though under what authority and on what terms, either of examination or of residence, they have not yet determined. They have the advantage of practically undivided counsels, of knowing what they want, and of having an indisputable cause of complaint. They are naturally supported by the whole influence of the medical schools of London, and it adds not a little to the complexity of the situation that those connected with University and King's Colleges prefer to throw in their lot with the other professional schools rather than to hold aloof and unite with the other Faculties of their own Colleges.

Of the several bodies concerned, it is possible that the Senate, or at least the Convocation, of the existing University may fear that the just value of its degrees, attained by fifty years' efforts, will be compromised by allowing teachers to have a voice upon the Senate. But they must see that if the University is forsaken by its two most important London Colleges after the secession of its only important provincial one (Owens College), and if the medical schools of London, which have supplied nine-tenths of its graduates in that Faculty, also forsake it, its position will be untenable. Even if it were suffered to exist as a degree-conferring machine for unattached and imperfectly-taught students all over the kingdom, it would become what its worst enemies have called it, a mere Government Board, and could scarcely keep the title of a University, still less of the University of London, when it had been stripped (or rather had stripped itself) of both characters. Moreover, Convocation would lose all importance, and could not possibly retain the only powers it at present possesses, of nominating certain members of the Senate and accepting new charters. The Senate would do its sole work, of choosing examiners and revising their lists, as a small body of salaried Government officials (probably in South Kensington), and no claim would remain for the unconnected waifs and strays who passed the examinations to take any part in the matter. No charters would be requisite, nor any apparatus of library or Senate House, laboratory or lectures. In fact all the efforts of the past twenty years would be thrown away.

Nevertheless, if the two original Colleges of the University secede, they will find the name, the prescription and the influence of the Senate too strong for them to wrest its powers from the present holders.

The medical corporations have far more influence and far stronger grounds; for the three or four strongest of them are organised as complete Colleges in their own Faculty, and give a more academic training to their students in medicine than either University or King's College does to students in arts, science, or laws. They might, perhaps, succeed in gaining power to grant degrees where the others failed, but this could only be by showing that no reasonable concessions were made to their just demands by the existing University.

Hence it will be seen that the present University of London, its two original Colleges, and the principal medical schools, have each of them the power of checking, if not of checkmating, each other's plans. Even if they agreed to urge their several objects without opposition to each other, the result would be three Universities existing together in London. One would have become a mere examining Government Board; another would consist of two ill-endowed and ill-consorted Colleges, without residence, with slender endowments, and compelled to extend their proper functions by attempting the instruction of partial students; the third would be a combination of two large professional corporations with Colleges in one faculty only, two or three well equipped, several very poorly furnished, and all of necessity rivals, scattered over the country, none of them endowed, and only able by the terms of their existence to give a second-rate degree.

What hope would there be of any one of these three so-called Universities even approximating to what a University of London should be? Each would be strong enough to prevent the others succeeding; none would be strong enough to absorb its rivals. Meanwhile the higher education would deteriorate rather than improve, endowments would be indefinitely postponed, and the prospects of the University laboratories, museums, and libraries of London sending out worthy contributions to the progress of human knowledge would become poor indeed.

When the several separate movements now in progress are checked by the necessity of obtaining the sanction if not the support of Government, we may hope that broader views will be taken of what is best for the community, and more sober views of what is practically attainable. Believing in the public spirit and the good sense of our countrymen, we have little fear but that, with patience and mutual concessions, a combined result will be obtained which will benefit all the parties to the new confederation, and promote the only interests with which this journal is concerned—the national interests of learning and of science.

A JUNIOR COURSE OF PRACTICAL ZOOLOGY

A Junior Course of Practical Zoology. By A. Milnes Marshall, M.D., D.Sc., M.A., F.R.S., Professor in the Victoria University, assisted by C. Herbert Hurst. (London: Smith, Elder, and Co., 1887.)

NOTICE will be found in the columns of this journal (vol. xxviii. p. 242) of the second edition of a small laboratory hand-book by the senior author of the above-named work, entitled "The Frog; an Introduction to Anatomy and Histology." In the preface to that we read: "The second instalment of the work, containing directions for the examination and dissection of a number of animals chosen as types of the principal zoological groups, is in active preparation, and will be published shortly." The author further acknowledges "valuable help from Mr. C. H. Hurst, Assistant Lecturer in Zoology in the College." Mr. Hurst now appears as junior author, and, although the work here under review differs in some important respects from its predecessor above referred to, we presume that it is the promised "second instalment."

The volume opens with an introduction, confined to the consideration of practical hints as to methods of working and manipulation; then follow fifteen chapters, each devoted to some one type of organisation, and the whole closes with an appendix, dealing with the uses and methods of preparation of reagents. We have, in all, a most successful and important book of 421 pages.

The work is largely akin, in its more salient features, to many of its predecessors; but it stands alone in respect of certain methods of treatment, to which we shall refer duly. Thick type has been employed throughout for the various headings, and the authors adopt the plan, introduced in the aforenamed smaller work, of printing the directions for dissection in italics. In dealing with the complications of the vertebrate skeleton, they have availed themselves of the printer's art, by way of restricting descriptions of homologous sets of elements to corresponding and distinct types.

The introduction is a model of perspicuity, and so well set as to render it impossible for the veriest tyro to obtain anything but full benefit therefrom. The advice given is sound in the extreme, and such as could only have embodied the results of a long and well-tried experience. The directions for injecting blood-vessels are, perhaps, a little too elaborate, being worthy of the *préparateur's* art, rather than of the ordinary beginner; this, however, is a small defect on the right side. We note that under the section on microscopical examination all reference to the micrometer has been omitted. Directions for measuring objects under observation should certainly be added to the next edition.

The several chapters into which the book is subdivided differ most conspicuously from those of certain earlier works in the fact that the more general statements made are diffused throughout the whole, except so far as they serve to define an animal under consideration, or to set forth the predominant characters of a given system of parts. The chapters on Protozoa and the Leech may be consulted as fair examples. In the latter, advantage is taken of this method to force upon the student, somewhat prematurely, the fact that (p. 36) "the segmental arrangement affects in a marked manner the nervous, excretory, and reproductive systems, and, to a less degree, the circulatory and digestive organs," and the deduction that "it appears to result from a definite arrangement of parts which, in the ancestors of the leeches, were scattered irregularly through the body, much as in *Fasciola*" (dealt with in the previous chapter).

By way of contrast with its predecessor on the Frog, this volume is shorn of much that is histological. In the earlier work a special feature was made of this branch, but here it by no means receives that amount of attention which its importance demands. A start in this direction might well be made with the lung-structure of the bird and mammal, especially in view of the statement made (p. 389) concerning the mechanism of respiration in the former.

The detailed descriptions of the various animals chosen are, for the most part, exceedingly well rendered. A slight ambiguity has crept in in one or two places, and the descriptions of the vascular systems of the mussel and snail might well be amplified.

No portions of the descriptive text stand more in need of revision than those relating to the digestive glands. These are, in Anodon, Helix, Astacus, and Amphioxus, designated under the old term "liver." A certain amount of justification is forthcoming in the last-named case, in view of its blood-supply; but in the three first-named the striking results of recent research, which call for no comment here, ought at least to be suggested in the term "digestive gland" or "hepato-pancreas." While we would see, thus, the substitution of a modern term for one well-nigh obsolete, we would desire the withdrawal of the terms "kidney" and "ureter" as applied to the excretory organs of the Invertebrata. In the case of the mussel, in which a portion of that which our authors term "ureter," is glandular and secretory, the terminology as restricted by them becomes misleading.

Conspicuous among the novelties offered us are certain words new to students' books. The volume is fully up to date, and its authors are to be congratulated on having produced the first book for students in the language, which describes the receptaculum ovorum of the worm. As regards pure nomenclature, it is worthy of note that they have embodied, in describing the pterylosis of the bird's wing (p. 386), that introduced by Prof. Flower so recently as February 1886, in a lecture delivered at the Royal Institution; and necessitated by the splendid work in which he is being assisted by Mr. R. S. Wray. (The description of the barbules on the same page is in error.)

In dealing with the appendages of the insect, the nomenclature customarily applied to the crustacean limb is utilised. To this extension we heartily assent. On turning to the crustacean itself, we meet with an innovation far less deserving of support. Our authors, faithful to precedent, reduce the body of the decapod crustacean to twenty segments; but in so doing they discard the ophthalmic somite of their seniors, and press the telson into the service. This introduces a serious difficulty when the nervous system is taken into consideration, and a still more formidable one as concerns the homology of the eye-stalk. That is passed over in comparative silence, and, although we are not told so in as many words, it is clear that they regard it as in no way serially homologous with the appendages. The condition of the visual organ in the lower Crustacea and other arthropods, taken in conjunction with the facts adduced by Brandt and others in the morphology of the insect's eye, render it probable that the above view may turn out to be correct. Nor must it be forgotten that Boas has challenged (*Morpholog. Jahrbuch*, vol. viii.) the accepted interpretations of the antennule. There are, however, two sides to this question, and it is important to observe that M. Alphonse Milne-Edwards has recently described a decapod (*Palinurus penicillatus*, *Comptes rendus*, vol. lix., 1864), in which one ophthalmite was for the most part multiarticulate and antenniform. This remarkable fact is the more striking in view of the reversion to the antenniform type of certain post-oral appendages, seen in *Mastigopus* and *Apseudes* among the Crustacea, and so well known in the scorpion-spiders; whatever may be its precise significance, it is clear that the question of general homology of the eye-stalk, with which we are here especially concerned, is far from settled. The introduction of so sweeping a change into a book for juniors without due comment is, under these circumstances, a false step, especially when it is considered that the precise converse is stated in all other books current.

Equally unjustifiable, in that it affects another debatable question, is the statement (p. 379) that the bird's pre-pubic process corresponds to the pubis of mammals. Clear proof of this is not forthcoming. The student's hand-book is not the place for such dogmatisms: if asserted, they should be well qualified, and put as alternatives.

The retention of the old nomenclature for the bird's air-sacs, with its atrocious "*thoracic*" element, is disappointing; the substitution (p. 220) of "pericardio-*cœlomic*" for the well-tried pericardio-peritoneal canal of the fish is as misleading as it is misjudged; while that of "*connective*" for the time-honoured commissure is, on the whole, inadvisable. We live in a word-mongering age. New terms which do not mark a turning-point in advance, or at least the era of a new discovery, are stumbling-blocks, unless introduced by way of replacing irrelevant or absolutely fantastic precursors. Such is not the case with those here under consideration. Our position is somewhat that of the port-bound crew, in dread of being stranded on their own beef-bones.

Attention has been already directed to the diffusion of the more general matter throughout the text. This has been effected very successfully, and in well-chosen language deserving of the greatest praise; but we dissent from the method adopted. It will be generally admitted that Huxley and Martin's "Elementary Biology" dissipated for students of the subject, once and for ever, the subtle "cram"; and subsequent writers working along similar lines have, as was to be expected, attempted to improve upon the plan therein created, each after his own lights. Messrs. Marshall and Hurst have aimed at producing a work which they hope "may meet the wants of those who desire to obtain a practical acquaintance with the elements of animal morphology, and who find the existing manuals insufficient for their purpose." It is to be assumed that they have been especially mindful of the needs of their own College, but the work also covers most of the requirements for the elementary examinations of other schools, and we presume the authors would wish it a general circulation among pure devotees. This said, we proceed to inquire into the method of treatment, and find with much regret that, at the outset, such deductions as are incorporated in the text almost invariably precede the description of those facts upon which they are based. For example: on p. 141, the alimentary canal of the crayfish—itself complicated—is ushered in with the words that it is "a tube running in a nearly straight line from mouth to anus. Of this tube, the middle portion, or mesenteron, which is very short, is alone formed from the primitive alimentary tract of the embryo, and the 'liver' is an outgrowth of it. The stomatodæum, or anterior portion of the canal and the proctodæum, or hind portion, which together form almost the whole length of the canal, are both formed by invagination of the external surface of the body; and both have a chitinous lining which is continuous, at the mouth and anus respectively, with the chitinous external covering of the body." Then follows the detailed description. Again, the podical plates of the insect are twice mentioned before the student is told how to find them. The tympano-Eustachian passage of the bird is (p. 414) similarly treated; and here the generalisation given should, if introduced at all, have been rather inserted when dealing with the mammal, on the supposition that, as can hardly be doubted, the authors would have the student work over the animals in the order of presentation. In such cases as the dogfish skeleton (p. 198), the limbs of the mammal and bird (pp. 287 and 376), and the enumeration of the differences between Amphioxus and the higher Vertebrata (p. 168), the system is tolerable, by way of clearing the ground and exciting interest. When, however, as in the first-cited instance, the crowning triumph of the student's labour is thus anticipated and his reward forestalled, deduction on reflection upon his work falls flat, and one of the chief aims of the whole system is lost. This, to our thinking, constitutes the gravest defect in this valuable work.

In describing the rabbit's liver (pp. 306–7), the lobes are rightly enumerated, but the student is not informed upon what grounds the customary nomenclature is adopted. In this, and one or two other instances, explanatory clauses are needed, but not given.

The illustrations are excellent, reflecting the greatest credit upon all concerned, and artistic merit such as that of Fig. 28 cannot fail to strike the reader. Fig. 27 is unnecessarily complicated, too much having been attempted. The beautiful new figures of Amphioxus are especially deserving of praise; but more of them are wanted, in order to do justice to the excellent description which they illustrate. Comparison of this chapter with that on the liver-fluke calls for this increase in number, in view of the relative chances of the student's procuring specimens.

Being mindful of the difficulties of preservation of Amphioxus, it is to be regretted that, while full directions are given for cutting sections, those for preservation, which have led up to the splendid results incorporated in this work, should have been omitted. This, the more so, as the animal is to be obtained in the Channel Islands, and is therefore within reach of the native student (a fact which should be mentioned in the text).

In dealing with the higher vertebrates, the authors follow one of their predecessors in first describing the skeleton. We doubt the advantages of this system, especially as in this work we have an "almost entire omission" of the muscular system, held to be "of subordinate educational value." The book, taken as a whole, is highly welcome and most admirable. It is provided with an exceedingly good index, and presented in a form demanding our sincere thanks alike to authors, printers, and publishers. Taking it, in conjunction with its predecessors, into account, we have to congratulate the student of zoology upon his accessions. This volume yields ample return for the immense labour which its authors have bestowed upon it; it is well worthy of the school which they represent, and of its prototype above named.

It is significant that the only typographical errors which we have detected should be the occasional absence of i and r. This fact might repay a careful research at the hands of the printer.

The authors state in their preface that "corrections or suggestions from those who use the book will be very gratefully received." Having dealt above with the more important matters which occur to us, we append comments on some of the more obvious among those of wholly minor importance, noted in perusing the volume.

Before proceeding to do this, we wish to call attention to two matters of exceptional note: the first, the respiratory folds of the lining membrane of the fish's mouth; the second, the attachment of the styloid element of the rabbit's hyoid-arch to the paramastoid process. It is indeed remarkable, seeing that these structures are of such common occurrence, and that they have been presented to every native student of recent years, that there is not yet a text-book in the language, or out of it for the matter of that, in which they are described. This is the more surprising in the case of the respiratory folds, in consideration of their general development among the gnathostomatous fishes.

The Hydra. We cannot accept the description of the supporting lamella as the "mesoderm"; it is misleading if not erroneous

The Leech. There is no mention of the intermediary nerve.

The Earthworm. The description of the histology of the nervous system needs amplification, especially as concerns the distribution of the nerve-cells, by way of bringing out the nature of comparison with the other types. The account given of the blood-vessels is incomplete; the sub-intestinal trunk (described by Horst, *Niederland. Tidschr.* vol. xxxvii., and others) is not mentioned, that term being applied, in error, to the supra-neural vessel.

We strongly dissent from the description given of the œsophageal glands. Further investigation is necessary before we can accept their subdivision into the two categories here proposed. By our contemporaries, as by ourselves, much variation has been observed in their number and relationships, and we have seen examples in which all contained calciferous concretions and opened into the gut.

The Edible Snail. In describing the liver, the terms left and right have been transposed. Mention should be made of the salient features, in structure and distribution, of the teeth of the radula.

The Lancelet. To the description of the supposed excretory canals of Lankester (p. 178) there should be added that of the much more likely one of Hatschek (*Zool. Anzeiger*, vol. vii.). We accept the senior author's views on oviposition, but Quatrefages' observation should have been mentioned unless finally disproved.

The Dogfish. The remarks on ossification (p. 194) are erroneous. The statement (p. 211) that the labial cartilages probably "belong to the same category as the extra-branchials" is unfortunate, in view of Dohrn's discovery that the latter are displaced rays of the gill-septum.

In describing the relative positions of the roots of the spinal nerves (p. 252) the terms dorsal and ventral have been transposed. The description is irreconcilable with Fig. 36.

The Rabbit. The description of the shoulder-girdle needs revision, with respect to the coracoid element and the relations of the clavicle. The statements concerning the morphological value of the pisiform would be better free of bias, in view of the tendency of current research. In describing the pelvic girdle, mention of the cotyloid bone has been omitted, and consequently we find the statement that the pubis forms a portion of the acetabulum (cf. Parker, P.Z.S., 1882; also Leche and Krause, *Internat. Journ. of Anat. and Hist.*, vols. i. and ii.). The Eustachian cartilage is deserving of note.

The structural differentiation of the lining membrane of the stomach and base of the rectum need description. The duct of the infra-orbital gland is insufficiently noted; the description of the cæcum needs revision. It is interesting to find that the authors have not discovered the ducts of the rectal glands.

The statement explanatory of the uterus masculinus must be withdrawn or considerably modified, in face of Kolliker's belief that it is a derivative of the Wolffian ducts ("Entwickelungsgesch.," 2nd edition, p. 981). Its structural features and relationships are much more intelligible on this view.

The description of the fifth ventricle needs modification, and that of the spiral valve of the portal vein might well be inserted (Hyrtl, *Sitzb. Akad. Wien.*, 1879).

The Fowl and Pigeon. Note of the more important muscles of the syrinx, as also of the larynx of the mammal, might advantageously be added.

The ventricle of the olfactory lobe is not mentioned, either in the bird or rabbit.

In conclusion, we would wish to draw attention to the satisfactory manner in which the authors have apportioned the several chapters of this successful volume in accordance with their respective value—no light task of its kind. The thoroughness of the book is one of its most striking features.

G. B. H.

EMBRYOGENY OF THE ANTHROPOID APES

Recherches Anatomiques et Embryologiques sur les Singes Anthropoïdes. By J. Deniker. (Paris, 1886.)

THIS work was presented to the Faculty of Science of Paris as a thesis for the degree of Doctor of Natural Science, and was approved of by it as sufficiently meritorious to warrant the bestowal of that degree on the author. It consists essentially of a comparison of the fœtus of the gorilla and of the gibbon with that of man, and also with young and adult anthropoids.

The embryogeny of the anthropoid apes, notwithstanding the great interest which it presents, is unfortunately little known, probably owing to the difficulties of obtaining embryo specimens. The author has therefore done well to utilise the opportunity which presented itself to further our knowledge of the subject, by publishing the descriptive anatomy of the fœtus of the gorilla and the gibbon which he has had the opportunity of studying. His account of the anatomy of these specimens is rendered more valuable by the comparison he has made between them and the human embryo, and between them and the adult animals of their respective species.

The work begins by a careful description of the external characters of the embryo gorilla and gibbon: the attitude, external form, coloration, and integumentary characters are respectively detailed with much care. The placenta and fœtal membranes were fortunately preserved with the fœtus of the gibbon, and their characters are described and figured, but unfortunately these parts were not obtained with the young gorilla, and so could not be described. A *résumé* is given of the observations of Owen, Huxley, Turner, and others on the placentation of apes and monkeys. The next section contains an account of the weight and dimensions of the various parts of the body of the respective fœtûs. Of the former little can be said on specimens preserved in alcohol, but the dimensions of the entire body, the head, trunk, and extremities, are carefully detailed in a tabular form, with the corresponding measurements in the human fœtus at the fourth and fifth month, and of the adolescent gorilla. A second table shows the relations which the dimensions of the several parts bear to the length of the body, and a third table those between the trunk and the extremities, and between the different segments of the latter. These tables show several interesting points in regard to the proportions which the various parts of the body bear to one another in the course of development. During the second half of intra-uterine life the upper extremity in the anthropoids is much shorter in relation to the length of the trunk than in the adult, and the same relation holds good with respect to the length of the fore-arm as compared with that of the upper arm. In the human fœtus of the same age, on the other hand, the upper extremity presents almost the same proportions that it does in the adult. The relative length of the superior extremity as compared with that of the inferior changes likewise considerably in the course of development. Thus in man during the earlier stages of embryonic life the lengths of both extremities are almost equal, but in the anthropoid apes, at an early period even, the length of the superior limb exceeds that of the inferior.

The skeleton of the fœtus is next compared with that of the adult anthropoids. In treating this part of the body the author naturally devotes considerable attention to the various parts of the skull, and has drawn up several valuable tables of its measurements in the fœtus and adult. The second chapter on the skeleton is devoted to a description of the vertebral column, and the limb bones; while the third treats of the dimensions of the individual bones. The points of ossification of the skull are found to be the same in man and the anthropoid monkeys, but the rate of their development in the monkeys in many important respects differs from what obtains in man. In general it may be stated that the frontal region ossifies more rapidly, whereas the occipital and petro-mastoid regions ossify more slowly than in man. The cranial sections unite probably in the same order as in man, but generally at an earlier age, nevertheless there are certain exceptions to this which are pointed out. The brachycephaly of the skull of young anthropoids diminishes as age advances. Elongation of the facial part of the skull occurs much more rapidly than that of the antero-posterior diameter of the cranial part, until the eruption of the teeth. Passing on to the osteological characters of the rest of the skeleton, we find that the points of ossification of the borders of the vertebræ in the fœtus of the anthropoids do not appear in the same order as in man, as they seem to form simultaneously in all the regions of the vertebral column. The points of ossification of the pleurapophyses of the cervical and sacral vertebræ appear later than in man. This is especially the case in the sacral region of the gibbon. The spinous processes of the cervical vertebræ are shorter in the fœtus and young gorilla than in the adult. In the former the sacrum is broader, the coccyx longer, and the sternum larger, than in the latter. The different segments of the upper and lower limbs, except the carpus, ossify more rapidly in the anthropoid monkeys than in man; the lower limb ossifies, however, more slowly than the upper.

The muscular anatomy of the young and adult anthropoids is fully described and compared, and presents many points of considerable interest. Contrary to the opinion of Bischoff, the muscles of the face are found by the author to be very distinct, not only in the adult but even in the fœtal state. The arrangement of the muscles of the neck, fore-arm, leg, hand, and foot are particularly noteworthy, especially when compared with those in man.

The encephalon of the fœtal gorilla was found to weigh 28 grammes, and equalled a sixteenth part of the entire weight of the body. In the fœtus of both the gorilla and the gibbon the cerebellum is very small, and is completely covered by the cerebrum. The relative and absolute dimensions of the brain of the fœtal gorilla correspond to those of the human fœtus at the fifth month, but in its convolutions it was equivalent to those of the human fœtus at the sixth month, while the frontal lobe corresponds to that of a seven-months child.

The heart of the fœtal gorilla, though absolutely smaller than that of the human, is much greater in proportion to the size of the animal; it is also more voluminous than that of the adult of the same species.

The form of the hyoid bone of the anthropoid apes resembles that of man more nearly in the fœtus than in the adult. Its ossification takes place earlier than in man. The ventricles of the larynx of the fœtal gorilla resemble those of man, and are not continued into the laryngeal sacs.

The development of the dentary follicles of the gorilla and gibbon takes place earlier than in man. The eruption of the milk-teeth occurs in the same order as in man, except that in the gorilla the teeth of the upper jaw appear before those of the lower, that is to say, the reverse of what generally obtains in man. The cæcal appendages increase relatively to age in the gorilla, while in man the contrary appears to be the rule. The spleen of the fœtal gorilla differs in form from that of other anthropoids and from that of man, and resembles more nearly the spleen of a carnivore. The liver of the gorilla has the four-lobed type-form common to the majority of mammals, and in this respect differs from that of man and the other anthropoids.

The work concludes with a chapter on the general result of the author's observations, in which he confirms the statement made several years ago by Huxley that the structural differences between man and the Primates which approach nearest to him are not greater than those which exist between the latter and the other members of the order of the Primates.

OUR BOOK SHELF

The Geographical and Geological Distribution of Animals. By Angelo Heilprin, Professor of Invertebrate Palæontology at, and Curator-in-charge of, the Academy of Natural Science of Philadelphia. (London: Kegan Paul, Trench, & Co., 1887.)

THE author of this book tells us that, while anxious to present to the student a work of general reference, wherein the more salient features of the geography and geology of animal forms could be sought after and readily found, he also wished to call attention to the more significant facts connected with the past and present distribution of animal life, so as to lead to a correct conception of the relations of existing faunas. The need of such a work will be generally acknowledged, and, without doubt, this little volume of some 400 pages does to a great extent supply the need; but it may be that the time has not quite arrived for the appearance of a perfectly satisfactory work on the subject. Though the record of both geographical and geological distribution is a vast one, still there is a vast deal more of the record yet to come, and the very pages of Prof. Heilprin's work show what immense additions to the facts, and the deductions drawn from these are based on the as yet incomplete publication of the results of the *Challenger* Expedition. When the author has these results to rely on, we find a certainty of fact and a sureness of deduction which give confidence to a general reader or to a student.

The volume consists of three parts. In the first part the distribution of animals throughout space is treated of; in the second the succession of life, the faunas of the different geological periods, and the appearance and disappearance of species are dealt with; in the third the present and past distribution of individual animal groups is considered. On the many still debatable points the author is always judicious, giving when necessary the opinions both for and against; nor, as far as we have been able to judge, does he fail to call attention to difficulties that surround many of the problems he has to refer to. In reference to the subject of the appearance of species, we observe that he regards the once burning question of the animal nature of Eozoon as settled "through the negative researches of King, Rowney, Julien, and Mobius, the elaborate memoir of the last-named being conclusive."

For the class of readers for whom this work is meant, a glossary of the technical terms employed would have been very useful. Most of them can be learned on reference to original sources, but it would have been convenient to have them within the same cover.

Life-Histories of Plants. By Prof. McAlpine. (London: Swan, Sonnenschein, Lowrey, & Co., 1887.)

THIS book may be dealt with in a very few words. It professes to give the essential features in the life-histories of a considerable number of types. The descriptions are extremely scanty, but in spite of this, room has been found for many very doubtful statements. Thus we have Dodel-Port's speculations as to the fertilisation of red seaweeds by the agency of small animals quoted as if they were well-established facts (p. 184). Chara is spoken of as "a sort of transition stage" between the red and brown seaweeds (p. 199). We fail to find any grounds for this extraordinary statement. We are informed that in Selaginella "the rain or dew will settle in the hollow of the leaf, and help to float the zoosperms; but in Pinus their dry and motionless representatives are more exposed to the wind on the outer surface of the leaf" (p. 279). It would be difficult to frame a sentence more hopelessly inaccurate than this.

The following passage from the introductory chapter is worth quoting: "Morphology by itself is thus seen to be a matter of mechanism, revealing nothing higher than a combination of mechanical movements, harmonious in action and beautiful in execution; but physiology, dependent on structure for the interpretation of the phenomena of life and the causes thereof, seeks to reveal the inner life as well as the outward expression of it" (p. 10). It will probably be new to most of us to learn that morphology reveals movements at all, mechanical or otherwise.

At p. 179 "apogamy" and "self-fertilisation" are used as equivalent terms; at p. 138 Spirogyra is said to produce gonidia, and at p. 25 reproduction in Selaginella is said to take place by means of a true seed.

We have only cited a few examples of positive errors, but throughout the book the terminology is strange and confusing, even where not absolutely incorrect.

The book is presumably intended for students "cramming" for examinations, but even for this purpose we fear that it will prove worse than useless. - D. H. S.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.*]

Vitality, and its Definition

IT is perhaps desirable that I should offer a few words of explanation, by way of reply to several of your correspondents, who have commented upon certain statements in my recent address to the Geological Society.

In the first place, I think that any candid reader of that address will acquit me of being guilty of such presumption as to make a statement, on my own authority, concerning the vitality of seeds. My object was to contrast the greater stability of mineral structures with the lesser stability of animal and vegetable structures. Consequently I selected what I thought would be regarded as the *extreme* examples of prolonged vitality in the animal and vegetable worlds respectively. It was quite sufficient for my purpose that competent botanists have cited the case of the germination of seeds taken from ancient Egyptian tombs as authentic, and that a botanist of such eminence as A. de Candolle should assure us that it is "not impossible." As a matter of fact, I have been informed, however, by a reliable authority that experiments on the germination of seeds taken from mummies have very recently been conducted to a successful issue.

With respect to Mr. Herbert Spencer's definition of life, my object was not to find fault with it but to show that the differences between "organic" and "inorganic" matter are of so shadowy a kind as to defy definition. Even straining the meaning of the word "correspondence" so as to give it the force implied in the passage cited from the "Principles of Biology" by your correspondent Mr. Collins, I maintain that in those changes undergone by minerals to which I apply the term "physiological" there is a complete "correspondence with external sequences." When the temperature of a crystal is altered through a certain range, expansion and contraction take place unequally in accordance with the molecular structure of the mass. In consequence of this unequal expansion and contraction, stresses are produced and the crystal undergoes an internal molecular rearrangement, which is determined by a latent "organisation," though it can only be detected, perhaps, by its action on the light-waves. But now let another set of forces come into play, namely, the chemical action of liquids containing gases in solution, and immediately the effects of the former change are seen in the manner in which the crystal yields to the new forces operating upon it. This *secondary* change is in fact only rendered possible by the primary one having taken place. But the changes produced by solvent action in turn weaken the stability of the whole mass, permitting other chemical affinities to assert themselves, in consequence of which the crystal enters upon a long series of metamorphoses which terminate in the complete "dissolution" of the ties that held together its molecules; it thus becomes a pseudomorph, a sort of mineral corpse, with the external form of the original crystal only, but without any of that capacity for undergoing a wonderful cycle of changes which was its original endowment. After this the materials of the "dead" crystal may be used up to form the substance of new ones.

It is scarcely necessary to add that I had no serious intention of asserting that minerals do actually live, in the sense in which "living" is popularly understood. All I care to insist upon is that minerals, like animals and plants, go through definite cycles of change, dependent on their environment, and that the distinction between "organic" or "living" matter and "inorganic" or "lifeless" matter is therefore not a fundamental one. Surely no better proof of this can be adduced than the fact that the more exact we try to make our definitions of the terms "life" and "organisation," the more shadowy and intangible become the distinctions upon which we are driven to depend. I am perfectly satisfied with Mr. Herbert Spencer's admission of "insensible modifications and gradual transitions which render definition impossible." But if this be the case, it is surely not wise to maintain that the science of "non-living" beings must differ totally in its aims and its methods from that of "living" beings. To bring out into clear relief the analogies between the science dealing with the mineral kingdom and those concerned with the animal and vegetable kingdoms was the main object of my address.

"The *Gecko* moves its Upper Jaw"

THUS by the substitution of one reptile for another—of the gecko for the crocodile—the well-remembered zoological statement in Arnold's Greek prose is at length put upon a satisfactory foundation. In the spring of 1886, I captured a small gecko (*Tarentola mauritanica*) at Rome, and I have hitherto succeeded in keeping it alive and in health. One of the first things I noticed about it was the extraordinary vigour with which so small an animal would bite one's finger. And the effect produced was certainly rather due to the lizard's expression of intense ferocity during the process than to the pinch which it was able to give. The expression chiefly depends upon two things—the fact that the anterior part of the head may be bent downwards, and that the eyes are retracted into the head. Examining the former movement more carefully, it was seen that in opening the mouth the upper jaw is distinctly although slightly raised above the normal, so that the profile of the upper surface of the head becomes almost straight (compare Figs. 1 and 2). In biting fiercely it is common for the upper jaw to be depressed below the normal, as is plainly seen in a profile view (compare Fig. 3), although in other positions the curvature of the head is

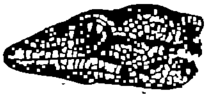

FIG. 1.—The Tarantola in the normal position of rest.

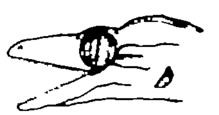

FIG. 2.—The Tarantola prepared to bite, with the upper jaw raised.

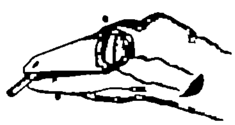

FIG. 3.—The Tarantola biting,—a common position, in which the upper jaw is depressed below the normal.

normal, and again in others the profile may remain straight in biting (as in Fig. 2). As far as I could observe in Tarantola, the upper jaw was always raised in opening the mouth, and the profile of the head straightened from its normal curve when at rest, but on closing the mouth in biting the movement of the upper jaw depended upon the relative position of the animal to the object which it was biting. This depression of the upper jaw may be also often witnessed when the mouth is closed, and it may be produced by applying slight pressure to the head. The animal seems to make the most of its powers of expression, for on provocation it opens its relatively huge mouth with the greatest readiness, and will keep it open for a considerable time, during which its appearance is sufficiently awe-inspiring. The fact that the anterior part of the skull is not co-ossified with the posterior part is well known. Thus in Huxley's "Anatomy of Vertebrata" (1871, p. 225) the following statement is made concerning the geckos: "Neither the upper nor the lower temporal arcades are ossified, the post-frontal being connected with the squamosal and the maxilla with the quadrate by ligament;" and Mr. Boulenger informs me that had he been asked whether the upper jaw of such lizards is moved in biting, he would have been inclined to answer in the affirmative, reasoning from the well-known condition of the skull. But I believe it has not been hitherto actually observed that such movable articulations possess a functional value in the living animal, and that the geckos must be added to the well-known instance of the parrots as Vertebrata which move the upper jaw in biting. It is extremely probable that the same observations will be found to hold for other families of lizards. EDWARD B. POULTON

Wykeham House, Oxford, March 1

Weight and Mass

TILL some quite new facts are discovered, such as shall force us to reconsider our convictions (which have not been lightly formed), I do not think it profitable to accept a quasi-metaphysical challenge from my friend Prof. Greenhill. He has at heart, as strongly as I have, the cause of *definiteness* and *accuracy*:—and if he, as is natural for one in his position, feels inclined to sympathise with the "vernacular" of Engineers rather than object to it as I do, there is nothing for it but to agree to differ. My remarks on this aspect of the subject were of the most cursory and general character; and I went so far as to say that, as the book in question was written by a practical man for practical men, "perhaps we ought not to complain."

I cannot, however, go *so much further* as to allow, with Prof. Greenhill, that it is "perfectly correct" to use the words pound or ton "side by side in two senses." As regards this practice I, in turn, must quote from an unpublished letter of Clerk-Maxwell's. [The passage purports to be part of a (reported) speech by a well-known Evolutionist.]

"He regretted that so many . . . . were in the habit of employing the word in a sense *too definite and limited* to be of any use in a complete theory. . . . . He had himself always been careful to preserve that largeness of meaning which was too often lost sight of in elementary works. This was best done *by using the word sometimes in one sense and sometimes in another*; and in this way he trusted he had made the word occupy a sufficiently large field of thought."

I have three other remarks to make upon Prof. Greenhill's letter:—

(1) He shows the absurdity of defining the weight of a body as "the force with which it is attracted by the earth." Of course such a definition must necessarily be absurd provided it comes *after* an explanation (given by Prof. Greenhill) that "weight" is to be understood in the sense of "mass." But from this explanation itself it would unfortunately follow that *a body has weight even when it is no longer heavy*; as, for instance, when it is in a (supposed) cavity at the centre of the earth! Prof. Greenhill says that "weight" is "used in ordinary language in most cases" in the same sense as "mass." Surely the great majority of men regard weight from the point of view of the sublime Porthos:—

"Ma vaisselle d'argent . . . . qui doit peser de mille à douze cents livres, CAR je pouvais à grande peine soulever le coffre qui la renferme, et ne faisais que six fois le tour de ma chambre en le portant."

(2) He also speaks of certain difficulties imposed by the "rules of language." I do not ascribe to them so lofty an origin. They are the offspring of the dogmatic ignorance which has peopled the realms of science with Centrifugal Force and its fellow monsters.

(3) He has commented solely on a passing remark in my article, and says nothing as to its main purpose. I hope, however, that he will eschew "statical" measures of force, and give his hearty aid as well as his good wishes in the war of extermination which must perpetually be waged against the too luxuriant undergrowth of the scientific garden:—the circle-squarers, the perpetual-motionists, and (in the case before us) *the measurers of potential energy in terms of horse-power*.

P. G. T.

An Error in Maxwell's "Electricity and Magnetism"

IT may be allowed to me to remark that the error mentioned on pp. 172 and 223 of NATURE has its origin really in Helmholtz's renowned paper ("Ueber die Erhaltung der Kraft," 1847, p. 67), and that it thence found its way into most of the text-books on electricity. It has sometimes been detected and hinted at; for the first time, I believe, in C. Neumann's paper published in the *Ber. d. k. sachs. Ges. d. Wiss*, at Leipzig (1871), "Elektrodynamische Untersuchungen mit besonderer Rucksicht auf das Princip der Energie." There we find (p. 436) the formula—

$$T\mathfrak{v} + T_1\mathfrak{v}_1 = T^2\mathfrak{w} + T_1^2\mathfrak{w}_1 - TT_1\frac{dV_{01}}{dt} + \frac{dF}{dt},$$

which is identical with the equation of energy given in NATURE, p. 223, if we put—

$$\mathfrak{v}_1 = A_1,\ \mathfrak{w}_1 = R_1,\ -TT_1V_{01} = T_m,\ F = T_e,\ \text{\&c.}$$

The formula is followed by the remark that it agrees entirely with the formula given by Helmholtz, the only difference being the last term $\frac{dF}{dt}$, which in the latter is wanting; thus we may say that by Helmholtz the potential energy of the system invariably is expressed by zero.

Being formerly unaware of Neumann's researches, I, by another way, came to the same results, see the paper "Das Princip der Energie in seiner Anwendung auf die ponderomotorischen und elektromotorischen Wirkungen des elektrischen Stromes," published in the *Sitzber. d. k. bohm. Ges. d. Wiss*, (*vide* NATURE, vol. xxxiii. p. 308). In this paper I have hinted at *one* probable cause of this and similar mistakes and their relatively difficult discovery, of which the repetition of the error in the *best text-books* is a decisive proof. This cause I believe to be the trivial circumstance that there is no consistent and generally accepted notation of the different forms of potential and energy. This renders the comparison of different writings on this subject sometimes quite perplexing. When, for example, two authors denote the *same thing*, the one by V, the other by $-V$, and when the first writes the expression $d(T_1T_2V)$ in the form—

$$T_1T_2dV + T_2VdT_1 + T_1VdT_2,$$

the other the *identical* expression $-d(T_1T_2V)$ in the form—

$$T_1T_2dV - T_2d(T_1V) - T_1d(T_2V),$$

it may happen that they themselves and also other readers overlook the difference of sign, and that they continue to reason as *if their* V *were identical*. Such mistakes occur oftener than is supposed. See the interesting note at the end of Sir William Thomson's paper on "Capillary Attraction," NATURE, vol. xxxiv. p. 369.

Could there not be found a means of avoiding the inconveniences caused by such mistakes and the loss of labour spent in detecting them? I dare not hint at the possibility of an international system of notations of the most important physical quantities; thoroughly consistent, and recommended by the highest scientific authorities; for the realisation of such a system would probably meet difficulties quite insurmountable.

Prague University, March 12 A. SEYDLER

Tabasheer

MR. DYER in his article on "Tabasheer" in NATURE of February 24 (p. 396), throws out the suggestion that the silica deposited in the joints of bamboo may have undergone a process of dialysis. It may be of some interest to him, and to your readers generally, to learn that plates of transparent compact silica, SiO_2, may be formed by dialysing the basic soda silicate. Four or five years ago I discovered this, and succeeded in producing plates a quarter of an inch in thickness and four inches in diameter, by placing the basic silicate of soda within a dialyser, which was floated on dilute sulphuric acid, 1 part to 20. The plate of silica was formed in the floated vessel. A similar result may be obtained by placing in a wide test-tube a portion of basic silicate. Taking care that the upper portion of the tube is quite free from adhering silicate, the dilute acid should be poured on to the surface of the silicate without disturbing it. After a few hours the silica is eliminated in a crystalloid form.

Possibly the first process may help us to understand how tabasheer may have been deposited, while the second may throw some light on the formation of raphides, carbonic or some other acid being the active agent.

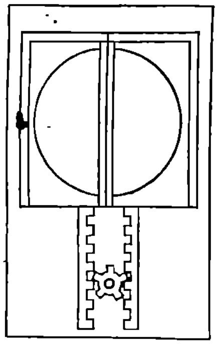
16 Savile Street, Hull, March 15 THOMAS ROWNEY

A Method of Illustrating Combinations of Colours

IN NATURE, vol. iv. p. 346, there is a description by Mr. Allen, of Sheffield, of some methods of showing the combination of various colours on a screen. He used a biunial or "dissolving view" apparatus to produce overlapping disks of colours, and also three lenses mounted close together in place of the ordinary single lantern objective, and giving images of three apertures in a lantern slide, close to which were placed cells of coloured liquids.

His experiments suggested to me the following method, which I have used for some years past, and for which only the ordinary single optical lantern is required.

A lens 10 cm. in diameter and 15 cm. focus is cut in half, and the two halves are mounted in frames so as to be capable of sliding past each other precisely in the same way as the divided object-glass of a heliometer. The motion is given by a pinion acting on racks in the same way as in the ordinary double-barrelled air-pump.



In the frames which carry the semi-lenses are cut grooves in which slips of coloured glass, or gelatine, or cells of coloured liquids may be placed; and the whole is fitted on the nose of the lantern in place of the usual objective, a diaphragm with round aperture about 3 cm. in diameter being put into the slide-holder.

Thus, when the two semi-lenses are so placed as to have their principal axes coincident, they act as a single lens and form one image of the aperture on the screen: but when they are moved past each other by turning the pinion, two disks of light are shown which can be separated entirely or made to overlap to any required extent. If, then, glasses or liquids of any given colours are placed in front of the semi-lenses, the compound colour produced by their union can be easily shown, either simultaneously with the component tints, or alone by accurately superposing the disks, thus avoiding any disturbing effect of the intrusion of other colours upon the eye.

It is in this way easy to show, taking four prominent colours, blue, green, yellow, and red, that blue + yellow = white; blue + red = purple; green + red = yellow, &c.

In place of coloured liquids, which are "messy" and liable to change, I almost always use coloured glasses, either singly or superposed (cobalt-blue, for instance, cemented to "signal-green" glass gives a good pure blue). Such glasses can by patient and careful selection be obtained of almost any required tint and intensity. H. G. MADAN

Eton College, March 26

Ice-Period on the Altai Range

IT is generally assumed that in the Altai Range there are no traces of so-called ice-ages. Hitherto, however, only ridges on the borders of the Altai Mountains have been examined. The geological phenomena of the mid-Altaic regions are still almost quite unknown. In the course of last summer it happened to me to visit some parts of the south Altaic regions—the Narim Range in the vicinity of Altaiskaia, Stornitza, or Koton Karagay, the neighbourhood of the Cossack settlement Oorool, then the so-called Katoon's Pales with their snowy giant Belooha. Subsequently I travelled in the valleys of the Belaia and Chernaia Berels, and visited the valley of the Arassan lakes and some other places. Everywhere I was struck by many and various traces and remnants of a large icy cover, which has left either strong glacier deposits, or abundant remains of moraines, or pieces of granite covered with lines. The valleys, too, bear on them the indubitable signs of glacial origin. In a word, there can be no doubt as to the existence of a large ancient icy cover here. Were these glaciers contemporaneous with the ice-age of Europe and North America, or do they present themselves as a quite independent system? My own observations convince me of their independence. The Altaic ice-period had, I think, its own causes. The Altaic system of mountains is of great antiquity; and its ridges were probably much higher at one time than they are now. Perhaps the whole system rose far above the line of eternal snow, although at present this line is reached only by some of the highest summits. It is probable, too, that in those very remote times the meteorological conditions of the country were far harsher than at present, because glaciers were more numerous and descended lower, digging the V-shaped valleys of the Katoon River, of the White and Black Berels Rivers, of Chindagatooy, &c.

The question of the periodicity of glacier-ages has again been raised lately, and perhaps it is from the Altai and from the Blue Alps that we may obtain the solid data for the complete solution of this very important question. A. BIALOVESKI

Oostkamenogorsk, November 1, 1886

A Claim of Priority

J'AI eu récemment l'occasion de lire dans le *Philosophical Magazine* (Août 1886) la description très-intéressante d'un "intégrateur sphérique," combiné par Mr. Frederick John Smith, et qui semble être une modification de celui du Prof. Hele-Shaw. Mais l'idée première de ces appareils, et c'est sur quoi je dois appeler votre attention, m'appartient sans doute, car dans le No. 630 du journal anglais NATURE (Novembre 24, 1881) j'ai donné la description d'un "Anémomètre Intégrateur," fondé sur le même principe, et qui a été plus tard cité dans le *Quarterly Journal of the Royal Meteorological Society* (No. 43, 1882), par Mr. Laughton ("Historical Sketch of Anemometry and Anemometers").

La modification imaginée par Mr. F. J. Smith, tendant à supprimer ou à amoindrir, autant que possible, le moment d'inertie de la sphère, me parait excellente, surtout s'il fallait transmettre des vitesses quelque peu considérables. Mais quand il s'agit simplement d'enrégistrer celle du vent sur une échelle modérée, je crois que la forme primitive suffit, et, d'après plusieurs essais que j'ai faits, une bille d'ivoire roulant sur des cylindres de bronze c'est ce qui donne les meilleurs résultats.

Je vous prie, Monsieur le Directeur, de vouloir bien faire constater dans votre estimable journal cette réclamation de priorité, ainsi que d'agréer mes plus sincères remercîments et l'assurance de ma considération très-distinguée.

Observatoire de Madrid, le 12 Mars V. VENTOSA

Oktibehite or Awaruite?

IN the notice of the proceedings of the Geological Society of London (NATURE, December 23, 1886, p. 190) the discovery in New Zealand of a nickel alloy allied to *oktibehite* appears to be claimed by Prof. Ulrich, of Dunedin. This requires explanation, as the mineral was first determined, and named *awaruite*, after the locality, by Mr. W. Skey, Analyst to the N.Z. Geological Survey Department on September 28, 1885, and described by him in a paper read on October 25, 1885, and published in the local papers at the time, as well as afterwards in the Transactions of the N.Z. Institute, vol. xviii., issued May 1886. A notice of it is also given in my twenty-first annual Museum and Laboratory Report, June 1886, of which I inclose a marked copy. It will be observed that while Ulrich accepts the identity of the New Zealand alloy with *oktibehite*, Skey's analysis shows that its formula is 2Ni + Fe, while that of the latter mineral is Ni + Fe.

AËRIAL VORTICES AND REVOLVING SPHERES

A STRIKING series of experiments on aërial vortices and revolving spheres has lately been made by M. Ch. Weyher, one of the directors of the important establishment for mechanical constructions at Pantin. An account of these experiments, with illustrations, appeared in a recent number of *La Nature* (February 26). As the results obtained by M. Weyher are very interesting, we reproduce the more important figures, and translate the descriptions given by our French contemporary.

Fig. 1.—*Aërial Vortices.*—A glass cylinder of about 0·40m. in diameter by 0·70m. in height, has an upper cover, pierced by a hole, through which passes the shaft of the drum, the latter being formed of one or two paddles of cardboard put cross-wise upon the vertical shaft.

The cylinder contains some sawdust, or, better still, some oatmeal. If the oatmeal is put at first so as to form a cone or mound, and if the drum is turned round, a little waterspout can be seen forming at the top of the mound. Gradually the mass of oatmeal sinks into a hemisphere.

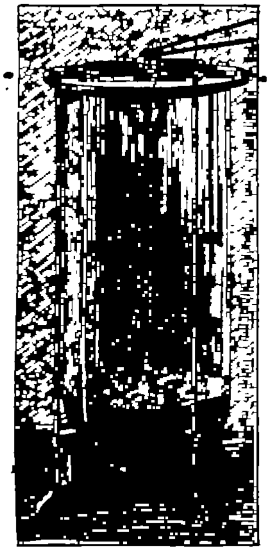

FIG. 1.

The matter runs without ceasing into spirals from the circumference to the centre; there it forms at first the lower cone, and then the upper reversed cone, in which the particles of oatmeal describe spirals, going from the centre to the circumference.

The whole system describes a primary general sphere, more or less distorted, the centre of which (where the two cones meet) is more or less deranged by the earth's gravity. If this is looked at from above, a hollow funnel is seen upon the axis: it is there that the air is most rarefied by rotation, and it is there that the finest particles come.

Substituting for oatmeal in the apparatus small light balloons inflated with air, the general movement can be followed. When the balloons are on the exterior circumferences, they fall in slow spirals; when they reach the circumferences nearer the axis of rotation, they rise rapidly upon a helix at a much more extended pace. In short, the experiment shows that, given a mass of air, if a movement of rotation round a vertical axis is imparted to it this air falls constantly by the exterior circumferences, and rises by the interior circumferences, and the *whole* volume passes unceasingly through the centre of the vortex, drawing into its movement the substances or particles therein immersed.

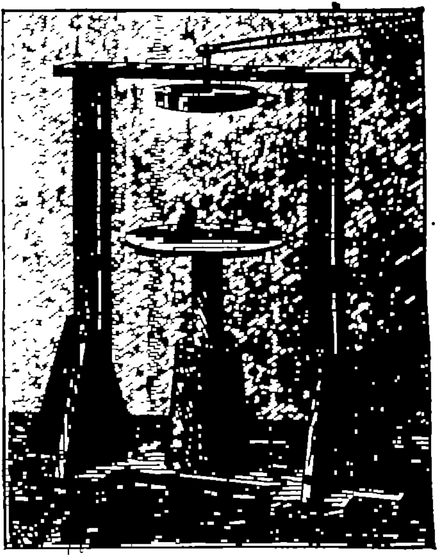

FIG. 2.

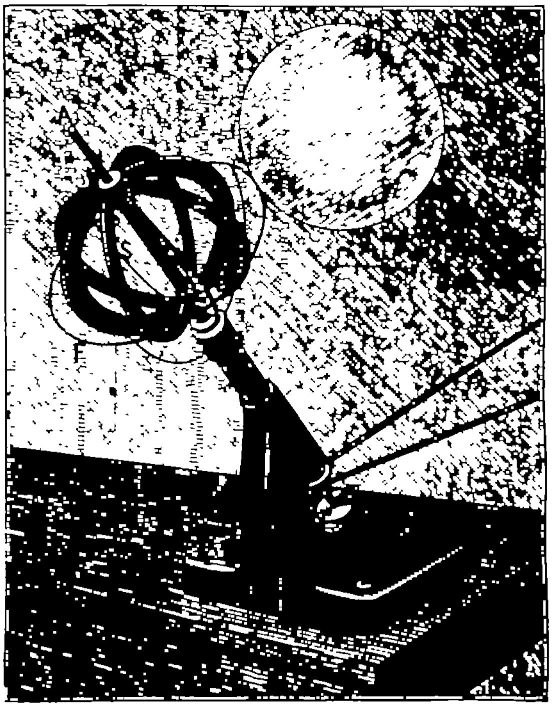

FIG. 3.

Fig. 2.—A plate of glass or any other material is placed below a drum with paddles; when this drum is put in

motion, we immediately place upon the plate a disk or a coin, to which the fingers give a first movement of rotation round one of its diameters.

The hand being quickly drawn back, the aërial vortex continues to make the coin turn round like a top, and absolutely keeps it captive in its radius of action. The coin, while turning upon one of its diameters, makes a sphere, and a later experiment will show that a revolving sphere constitutes a centre of attraction.

Fig. 3.—*Equilibrium of Revolving Spheres.*—A free sphere keeps itself in equilibrium, and turns round another sphere, to which a rapid movement of rotation is imparted.

The apparatus consists of a pin, A, which is able to turn in a support, and has a pulley, made to receive a transmitted movement. Upon the pin A is placed a sphere, S, composed of from eight to ten flat circular pieces (these may be either flat disks, or disks cut into a crescent shape; it does not matter which). The pin may be at any angle whatever to the horizon; in this experiment it is inclined at 45°, but it may be horizontal or vertical. The angle of 45° was chosen because it seemed to be most difficult for the experiment, which would therefore be the more conclusive. When the sphere S is turned round rapidly, you feel on the hand a strong blast which escapes all around from its equator. Bits of paper which are placed near it are thrown far away. Nevertheless, if a balloon is put near this blast, it is quickly attracted towards the revolving sphere, and describes orbits round it in the plane of the equator. As the experiment took place in a room, where there were obstacles producing eddies, and as also gravity has too much effect by reason of the proximity of the ground, it is very difficult to obtain a regular movement. The balloon comes easily in contact with the revolving sphere, and is then driven away by the collision too far to be caught again. A very simple contrivance consists in placing round the sphere S a wire guard or circle of iron, F, 1 millimetre in diameter, attached to the support by three similar wires.

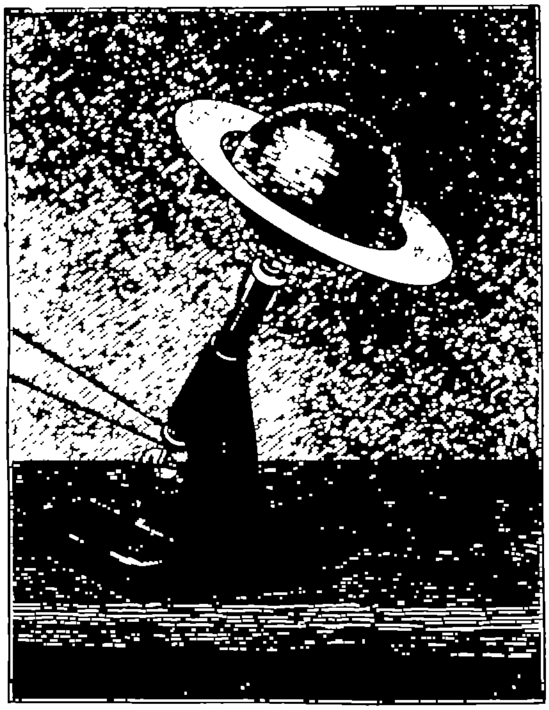

Fig. 4.

The balloon will then keep on turning round the motive sphere, even ceasing to touch the guard in the lower part under the action of gravity. The experiment can be made in different ways; and the guard may even be suppressed, but these variations teach us nothing new.

In studying the vortex movements which the sphere imparts in the medium in which it is plunged, we easily calculate the ratio of the attraction which it exercises on the balloon.

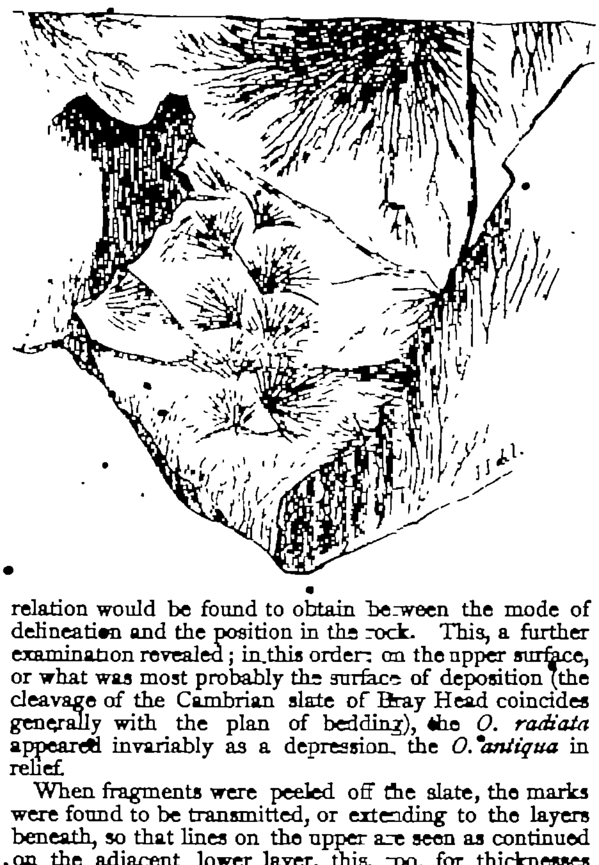
Fig. 4.—The guard of the revolving sphere is taken away, and we place parallel to its equator a circle of paper with an interior diameter greater than the exterior diameter of the sphere; the circle is caught into the movement of rotation, and maintains itself strongly in the plane of the equator.

ON OLDHAMIA

THE organic origin of Oldhamia has often been disputed. Originally described by Edward Forbes from specimens found at Bray Head, near Dublin, in rocks of the Cambrian formation, it has been found in a few other localities in Ireland, in rocks of a similar formation. In the dispute the weight of the evidence has seemed to be in favour of the views of Forbes, Jukes, Harkness, and Kinahan, that this lowly form is a fossil probably belonging to the Polyzoa, or to the Sertularian Polyps. So the matter has stood for a long time. A recent paper by Prof. W. J. Sollas, published in the Proceedings of the Royal Dublin Society for January last, once again opens the discussion. In the hope of throwing light on this problematical structure, thin slices for microscopic examination were cut, both parallel and transverse to its planes of cleavage. When these were placed under the microscope, all trace of the Oldhamia structure appeared to have vanished. An examination with the unaided eye showed, however, that it was still there, presenting itself as narrow, undulating, and branching bands of a lighter colour than the surrounding matrix. Its appearance, moreover, varied in an extraordinary manner according to the direction in which it was viewed. Looked at obliquely in a strong light, the thread-like bands are brilliantly illuminated, and appear faintly coloured with spectral tints; looked at directly, the bands become fainter, and are less clearly distinguishable from the matrix. In certain positions the slice taken at right angles to the bedding has an appearance somewhat suggestive of shot-silk, and, from the planes of cleavage, markings which remotely resemble in form the dendritic markings of Sutton stones extend into the surrounding matrix.

These appearances suggest the presence of some mineral possessing high reflection or refraction arranged in more or less parallel planes. Mr. Teall, in the same paper, gives full details of the mineral characters of the rock. Aided by these, Dr. Sollas finds that the lighter-coloured bands, which correspond to the Oldhamia markings, owe their distinction from the surrounding matrix to the presence of an excess of sericite scales; and that the curious shot-silk appearances are produced by the local deflections of these scales from parallelism with the cleavage planes into directions tangential to curves, which are probably transverse sections of those long ridges which, when seen on the exposed surface of a cleavage plane, are recognised as the usual form of Oldhamia. It would appear possible that these ridges are wrinklings of the cleavage planes produced during the shearing which led to their formation. These observations were made on the form known as *O. radiata*, and in some supplementary remarks Dr. Sollas adds that when Oldhamia is present it shows itself on the surface of the laminæ as rounded discontinuous ridges, which are without definite boundaries, and have the appearance of fine wrinkles. When the phyllode is fractured obliquely to the cleavage laminæ, the Oldhamia markings are found to extend through the rock as fine ridges or wrinkles which mark the surface of oblique fracture in a similar manner to those of the cleavage face. In fact, the appearances are remarkably similar to those of *ausweichungs-clivage*, described by Heim in his "Gebirgsbildung"; but the observations throw no light on the remarkable radiate form sometimes assumed by the structure. In a paper in the same journal Mr. Joly mentions that, in examining specimens of *O. antiqua* and *O. radiata*, he detected the following peculiarity: a sunken or depressed delineation of one form accompanied a raised or relieved delineation of the other form. Thus, if on any specimen *O. antiqua* appeared as a depression, on that same surface the *O. radiata* appeared in relief.

From this observation it appeared probable, if any meaning was to be attached to the relation, that a further relation would be found to obtain between the mode of delineation and the position in the rock. This, a further examination revealed; in this order: on the upper surface, or what was most probably the surface of deposition (the cleavage of the Cambrian slate of Bray Head coincides generally with the plan of bedding), the *O. radiata* appeared invariably as a depression, the *O. antiqua* in relief.



When fragments were peeled off the slate, the marks were found to be transmitted, or extending to the layers beneath, so that lines on the upper are seen as continued on the adjacent lower layer, this, too, for thicknesses exceeding a millimetre. The accompanying woodcut recalls the appearance of a surface of rock in which this is fairly well shown.

ON THE DISTRIBUTION OF TEMPERATURE IN THE ANTARCTIC OCEAN[1]

In the regions of the Antarctic Ocean where icebergs are numerous, and where in winter the sea-water freezes, the distribution of temperature in the deeper layers of water is peculiar. The facts are detailed in the "*Challenger* Narrative" (vol. i.). The general result of her observations went to show that, from the most southerly station, a wedge of cold water stretches northwards for more than 12° of latitude, underlying and overlying strata at a higher temperature than itself (p. 418).

Although the conditions and facts likely to throw light upon the cause of the existence of this cold intermediate or superficial stratum overlying water which at any rate in its upper layers has a temperature higher than that of freezing distilled water are discussed, no satisfactory explanation of the phenomenon is given. One important fact is noticed at page 421. "The fact that the cold wedge above referred to extended north just as far as the icebergs did in March 1874 points to there being some connexion between the temperature and the presence of melting icebergs." It is well known that icebergs consist of land-ice, which is as nearly as possible pure frozen water, and melts in the air at 32° F. It was thought that the effect of immmersion of such a substance in a medium having a temperature 3° F. lower than its melting-point would be to indefinitely preserve it, that in fact only the lower surfaces of the icebergs large enough to reach to a depth of 300 fathoms would suffer any melting at all. The existence of the cold stratum was ascribed wholly to the cold brine, separated from the ice on the freezing of the sea-water, sinking downwards with an initial temperature of from 28°·5 to 29° F. This cause, though existing and in operation, is quite inadequate to produce the effect observed. In Dr. Otto Pettersson's admirable work "On the Properties of Water and Ice," undertaken in connexion with the work of the *Vega* Expedition, there is a footnote at page 318 where he says: "As a thermometer immersed in a mixture of snow and sea-water *which is constantly stirred* indicates – 1°·8 C., we may regard this as the upper limit of the freezing and the nether limit of the melting temperatures of sea-water." In a review of Dr. Pettersson's work in NATURE (vol. xxviii. p. 417) I expressed doubt of the accuracy of this observation, but on repeating it I found it to be confirmed. It affords a complete explanation of the cold wedge of water in the Antarctic Ocean and the dependence of its thickness on the range of icebergs. These enormous islands of ice, a very large proportion of which rise in tabular form to a height of 200 to 300 feet above the sea, float in many cases with their lower surfaces at a depth of from 250 to 300 fathoms. The warmer and denser water coming from lower latitudes (see "*Challenger* Narr." vol. i. p. 428) bathes these lower surfaces, the temperature of the mixture at the surface of contact falls, the heat abstracted from the sea-water melts a corresponding amount of the ice of the iceberg, and a saline solution is produced, less salt and therefore lighter than the water away from contact with the iceberg, and having a temperature which depends immediately on the strength of the resulting solution. Being lighter than the surrounding water, this resulting solution necessarily flows up along the sides of the berg to the surface, and its place is taken by fresh undiluted sea-water which in its turn is cooled, diluted, and transferred to the surface. The result is the production of a most energetic engine of circulation and means of cooling and equalising the temperature of the water within the reach of icebergs. As there is continual renewal of the ocean water brought into contact with the ice, and as its composition is constant, the temperature produced is practically constant, namely 28°·8 to 29°·0 F., or – 1°·7 to – 1°·8 C. The layer of lighter water from 50 to 80 fathoms thick at the surface is due principally to this melting of land-ice, though it is also due in very small proportion to the melting of sea-ice.

Table giving the temperature at which ice melts in sea-water containing different percentages of chlorine

Temp. C.	1°·0	1°·1	1°·2	1°·3	1°·4
Per cent. Cl... ...	1·040	1·131	1·222	1·313	1·404
Temp. C.	1°·5	1°·6	1°·7	1°·8	1°·9
Per cent. Cl	1·495	1·586	1·678	1·769	1·880

This table is taken from a paper on ice and brines, communicated to the Royal Society of Edinburgh on March 21, 1887.

---

[1] Abstract of a paper read by Mr. J. Y. Buchanan before the Royal Society of Edinburgh, March 21, 1887.

The density (at 15°·56 C.) of the sea-water which comes in contact with the lower surfaces of the icebergs is 1·0255, which represents a chlorine percentage of 1·90. Ice actually *melting* in this water would produce a temperature of −1°·92 C. When ice is *immersed* in this water it lowers its temperature, and a portion of the ice is melted, producing dilution. The concentration, therefore, or chlorine percentage, which will determine the melting temperature of the ice, will be a little lower than that of the original sea-water. From the *Challenger* observations we see that, on the confines of the pack-ice the cold stratum of water has a uniform temperature of 29° F. (−1°·67 C.). Ice melts at this temperature in sea-water containing 1·65 per cent. of chlorine. In this process ice is melted, so that 100 grammes pure warm sea-water become 119 grammes of diluted cold sea-water. It will be observed that the ice which has been formed in the atmosphere at a temperature of 32° F. comes in this way to be melted at a temperature of 29° F.; and the pressure exerted by the 300 fathoms of sea-water, though it may assist in the lowering of the melting temperature, is insufficient to account for the amount.

TO FIND THE DAY OF THE WEEK FOR ANY GIVEN DATE

HAVING hit upon the following method of mentally computing the day of the week for any given date, I send it you in the hope that it may interest some of your readers. I am not a rapid computer myself, and as I find my average time for doing any such question is about 20 seconds, I have little doubt that a rapid computer would not need 15.

Take the given date in 4 portions, viz. the number of centuries, the number of years over, the month, the day of the month.

Compute the following 4 items, adding each, when found, to the total of the previous items. When an item or total exceeds 7, divide by 7, and keep the remainder only.

The Century-Item.—For Old Style (which ended September 2, 1752) subtract from 18. For New Style (which began September 14) divide by 4, take overplus from 3, multiply remainder by 2.

The Year-Item.—Add together the number of dozens, the overplus, and the number of 4's in the overplus.

The Month-Item.—If it begins or ends with a vowel, subtract the number, denoting its place in the year, from 10. This, plus its number of days, gives the item for the following month. The item for January is "0"; for February or March (the 3rd month), "3"; for December (the 12th month), "12."

The Day-Item is the day of the month.

The total, thus reached, must be corrected, by deducting "1" (first adding 7, if the total be "0"), if the date be January or February in a Leap Year: remembering that every year, divisible by 4, is a Leap Year, excepting only the century-years, in New Style, when the number of centuries is *not* so divisible (*e.g.* 1800).

The final result gives the day of the week, "0" meaning Sunday, "1" Monday, and so on.

EXAMPLES

1783, *September* 18

17, divided by 4, leaves "1" over; 1 from 3 gives "2"; twice 2 is "4."

83 is 6 dozen and 11, giving 17; plus 2 gives 19, *i.e.* (dividing by 7) "5." Total 9, *i.e.* "2."

The item for August is "8 from 10," *i.e.* "2"; so, for September, it is "2 plus 3," *i.e.* "5." Total 7, *i.e.* "0," which goes out.

18 gives "4." Answer, "*Thursday.*"

1676, *February* 23

16 from 18 gives "2."

76 is 6 dozen and 4, giving 10; plus 1 gives 11, *i.e.* "4." Total "6."

The item for February is "3." Total 9, *i.e.* "2."

23 gives "2." Total "4."

Correction for Leap Year gives "3." Answer, "*Wednesday.*"

LEWIS CARROLL

NOTES

IN the Report submitted yesterday at Edinburgh to the half-yearly general meeting of the Scottish Meteorological Society, the Council state that the work at the Ben Nevis Observatory continues to be carried on by Mr. Omond and the assistants in the same highly satisfactory manner as has been recorded in previous Reports. In addition to the laborious work of observing at all hours of the day and night, of reducing the observations, and forwarding copies for the Society and the Meteorological Council, the staff of the Observatory has given very effective assistance in the preparation of the tables of the meteorology of Ben Nevis now in the press. Several interesting researches are being conducted at the Observatory, the results of which will be communicated to a future meeting. The Directors took steps last autumn to raise subscriptions to clear off the debt on the institution, and to establish a low-level station at Fort William, at which hourly observations may be made for comparison with those at the Observatory. It is only by two sets of observations at the top and bottom of the mountain that the Ben Nevis Observatory can be utilised, with the desired success, in the furtherance of meteorological science, but particularly in that branch of it which concerns the improvement of the system of forecasting the weather of the British Islands.

ON Tuesday evening last the Lord Advocate stated in the House of Commons that the Scottish Universities Bill would shortly be introduced.

THE Paris Medical Faculty has decided to alter considerably the mode of competition for its Fellowships. The general object of the changes is to secure more original workers. The thesis (which has usually been the work, not of the candidate himself, but of his friends) is to be suppressed. Each candidate will henceforth have to deliver a lecture on his own scientific researches.

THE French Chamber of Deputies has decided that the buildings of the College of France shall be considerably enlarged. Fifty years ago, when this institution had only seventeen professors, its present buildings were sufficient; but now, when it has forty-one professors, they are very inadequate. It is to have four new lecture-rooms, a geological gallery, a set of rooms for other collections, a library, a meeting-room for professors, and eight laboratories. These additions will cost over 9,000,000 francs.

THE Anatomical Society, founded last September at Berlin, will hold its first general meeting at Leipzig on April 14. The Society has now over 170 members in England, Germany, Austria, Hungary, Switzerland, Holland, Belgium, Scandinavia, France, Russia, Italy, and North America.

DR. HANS REUCH, who has lately devoted much time to the study of earthquakes in Norway, has issued a tabulated circular, which has been reproduced in the entire Norwegian Press, requesting that reports of any phenomena observed in connexion with earthquakes may be sent to him. By Government permission all such reports may be transmitted through the post free of charge. Dr. Reuch asks especially for information on the following points: exact time of occurrence of the earthquake; the time compared with that of the nearest railway or telegraph station; locality of occurrence, and whether felt indoors or in the open; nature of soil; what the observer was occupied with; how many shocks were felt; nature of motion, undulating or oscillating; from what direction the shock came; whither it went; how long the motion lasted; what were its effects; did the shock resemble others experienced by the observer; was there any sound; was the sound heard before or after the earthquake; what was the interval between the shocks; were phenomena of restlessness in animals, or peculiarities of the weather, observed; if near sea or lake, were there any strange motions in the same; the names of any other persons who are known to have noticed the earthquake. Earthquake phenomena having been more than usually frequent in Norway during the past year, it is believed that Dr. Reuch's circular may be of considerable service to science.

At a meeting of the Japanese members of the Seismological Society of Japan held at the Imperial University on January 20 (according to a report in the *Japan Weekly Mail*) two papers were read in Japanese. The first was by Mr. Kikuchi, on the geology of Corea. In it the writer described the geological map made by Prof. Gottsche, who visited that country after leaving Japan. The paper also gave a description of the geological formations and the minerals found in the different provinces of Corea, and showed that Corea differs from Japan in the fact that these formations in the former country are much older, and on that account more stable, than those in the latter. This, Mr. Kikuchi thought, might account for the comparative absence of seismological phenomena in Corea. The second paper, by Mr. S. Sekiya, was on recent destructive earthquakes. The writer described in succession the causes and effects of the earthquake which occurred in Japan on February 22, 1880; the earthquake at Ischia in 1883; the shock of October 15, 1884, in Japan; the earthquakes in Spain in 1884; those of the United States of last year; and the shock of January 15 in Japan. It was pointed out that the three earthquakes mentioned as occurring in Japan were very similar in their intensity, and that they extended over nearly the same area; but, with regard to their place of origin, the writer said the first two shocks originated in Tokio Bay, or in the ocean beyond the peninsula, while that of the present year originated in a spot to the south-west of the two previously mentioned. A third paper on the meteorology of Tokio was postponed. It appears from this and other reports which we have published from time to time that the Japanese Section of the Seismological Society, where the papers are read in the Japanese language, is, like the parent Society, in a very flourishing condition. It evidently supplies a demand for this department of science amongst Japanese who know no language well except their own.

At the first meeting of the London Commission for the Melbourne Centennial International Exhibition, held on Thursday, the 24th inst., the chairman, Sir Graham Berry, said that the proposed buildings of the Exhibition would cover an area of more than 1,000,000 feet. It was decided that a deputation should ask Sir Henry Holland to take steps for the appointment, in connexion with the Exhibition, of a Royal Commission for the United Kingdom, and that the Foreign Office should be requested to communicate on the subject of the Exhibition with foreign Powers, India, and colonies other than Australasia.

On Saturday evening last, a lecture on "The Habits of Ants" was delivered by Sir John Lubbock in the theatre of the Working Men's College, Great Ormond Street. The lecturer gave an interesting account of some of the results of his own observations, and brought forward much evidence to prove that ants possess "something more than mere instinct."

By an Order in Council, dated March 7, Her Majesty has declared that the following antiquities shall be protected by the Ancient Monuments Act: (1) Little Kit's Coty House, or the countless stones of Tottington, at Aylesford, in Kent; (2) the chambered tumulus at Buckholt, in Gloucestershire; (3) the Druid's circle and tumulus on Eyam-moor, in Derbyshire; (4) the Pictish tower of Carloway, in Ross-shire; (5) the Ruthwell Runic cross in Dumfriesshire; and (6) St. Ninian's Cave, at Glasserton, in Wigtownshire. The Order will not come into force until it has lain for forty days before both Houses of Parliament.

In the so-called Seelberg, where in 1816 the mammoth group which is the chief ornament of the Stuttgart Museum was found, further excavations are being made under the direction of Dr. Fraas. Many skeletons, weapons, and implements have been discovered, and Dr. Fraas is of opinion that the mammoth group found seventy years ago was artificially put together by prehistoric artists.

In the *American Naturalist* there is an article by Mr. John Murdoch on what he calls "some popular errors in regard to the Eskimos." One of these "popular errors" is the notion that the Eskimos pass the winter "in a sort of hibernation, in underground dens, living in enforced idleness and supporting life by stores of meat laid up in less inclement seasons." Mr. Murdoch, who spent two winters at Point Barrow, says this is a wholly mistaken impression. In spite of the extreme inclemency of the climate, the winter, he asserts, is passed by the Eskimos "in one continued round of activity," and he gives a very interesting description of the manner in which they occupy themselves. Another "popular error" on this subject is the idea that the Eskimos always eat their food raw, and devour enormous quantities of blubber. At Point Barrow, Mr. Murdoch found that food was habitually cooked, although certain articles, like the "black skin" of the whale, were usually eaten raw. Taking into account the fact that the Eskimos have no butter, cream, fat, bacon, olive-oil, or lard, he doubts whether much more fat is consumed by them than by civilised peoples. At Point Barrow the fat of birds and the reindeer was freely partaken of, but comparatively little actual blubber either of the seal or whale was eaten. "Seal or whale blubber was too valuable,—for burning in the lamps, oiling leather, and many other purposes, especially for trade."

A book on "Sensation and Movement," by M. Ch. Féré, of Paris, has just been published. The author tries to show how different sorts of sensations react upon the vasomotor and motor phenomena, as indicated by pletysphygmograph and dynamometer.

In a work on "The Nationalities of Bohemia," lately published, Dr. L. Schlesinger shows that 37·11 per cent. of the population of that country are Germans, and 62·83 are Czechs. The limits within which the languages of the two races are spoken are generally very sharply drawn. There are 13,184 inhabited places in Bohemia, and in 4304 of them German alone is spoken, in 8473 the Czech language alone. In only 407 places are both languages used.

The death is announced of Prof. Simon Spitzer, Professor of Analytical Mechanics at the Technical High School of Vienna, the author of various well-known mathematical works. He died on March 16 at the age of sixty-one.

The new University building at Upsala is approaching completion. It has been in course of erection since 1879, and will be one of the finest University buildings in Europe. It will be opened with great ceremony on May 18 next by the King of Sweden, in presence of delegates from the principal foreign Universities.

LAST week the American Government forwarded another consignment of whitefish ova to the National Fish-Culture Association. These have been taken from late spawners, and appear more healthy than the batch sent in January. The ova are well "eyed," and in some cases are on the point of incubation. A consignment of the Californian trout ova, viz. the Rainbow (*S. irideus*), has likewise been received by the Association from the American Government. This variety is likely to become highly popular in England on account of its unique colour and form and its capacity of gaining flesh rapidly.

WHEN the South Kensington Aquarium was closed, the sea-trout which had been maintained there were transferred to ponds in the Delaford Park Fishery; and in February last many ova were taken from them and crossed with the *S. fario*, as in previous years. There are now a large number of hybridised examples of *S. trutta* in the ponds produced from ova shed in the South Kensington Aquarium and crossed in a similar manner. The two-year-old specimens are now about 7 inches long, their size being much smaller than that of other trout of the same age. None of the fish have spawned.

THE meaning of the word "scientist" seems to be rather vague in the country in which it originated. In his annual address as President of the Philosophical Society of Washington, lately published, Mr. John S. Billings says the word was a coinage of the newspaper reporter, and, "as ordinarily used, is very comprehensive." Webster defines a scientist as "one learned in science, a *savant*." Mr. Billings, however, thinks that the suggestion conveyed by the word "is rather that of one whom the public suppose to be a wise man, whether he is so or not; of one who claims to be scientific." In his address, the subject of which is "Scientific Men and their Duties," he himself uses the term "in the broadest sense, as including scientific men, whether they claim to be such or not, and those who claim to be scientific men, whether they are so or not."

PROF. SARGENT, Director of the Arnold Arboretum of Harvard College, estimates that five foreign trees are planted in New England to one native. Yet, of all foreign trees introduced into America, the willow alone, he thinks, has qualities not possessed in a greater degree by some native. The European oak is perhaps the most unsatisfactory deciduous tree that has been experimented upon: it grows rapidly when young, but fails, when about twenty years old, from the cracking of the main stem, and then, after dragging out a wretched existence a few years longer, it miserably perishes. The Scotch pine dies long before reaching maturity, and the Austrian and the Corsican pine seem to be no better. The Norway spruce, which has been for many years the most widely cultivated foreign tree in Massachusetts, becomes decrepit and unsightly just at that period of life when trees should become really handsome in full development.

THE Sonnblick Observatory, in the province of Salzburg, Austria, is the highest in Europe, being 10,177 feet above the level of the sea. It was established chiefly through the exertions of M. Rojacher, proprietor of the mines in that district, in conjunction with the German and Austrian Alpine Club, and the Austrian Meteorological Society. Telephonic communication was established with Rauris, a distance of 15½ miles, and observations were commenced in September 1886. Observations at such elevated stations offer much that is of interest to science generally, and more especially as regards those problems of meteorology which relate to the variations of pressure, temperature, and humidity in the upper regions of the atmosphere. In the *Meteorologische Zeitschrift* for February last, Dr. Hann gives an interesting account of the first three months' observations. The mean temperature in October was 25°·9 F.; in November 15°·3, and in December 8°·1. In October, the decrease of temperature with height during the barometrical minima was, generally, rapid. But during the barometrical maxima it was very slow in the lower strata, up to about 5900 feet; then an increase of temperature with height frequently occurred. The periods of high pressure were generally warm intervals on the Sonnblick, and the periods of low pressure were cold intervals. It is noteworthy, however, that the change of temperature with height, in the strata between about 5900 feet and the summit, was almost independent of the conditions of weather, being nearly constant during the whole month, and amounting to about 1°·3 F. per 328 feet (100 metres); while in the lower regions, from about 1300 feet to 5900 feet, it varied between 0° and 1°·1. And, generally speaking, the same rates of decrease of temperature obtained in November and December. During the period of high pressure, on October 1 to 5, which was the warmest part of the month, the march of relative humidity showed a great contrast at the high stations and at the valley stations, humidity being greatest at noon at the high stations, and lowest in the valleys. As regards wind, it may be remarked that early in November the anemometer became a shapeless mass of hoar frost. It remains to be shown what use can be made of the observations on such elevated stations for the practical work of weather-forecasting. The observers of the Pic du Midi claim to have foretold, from the conditions at that Observatory, the disastrous floods that occurred in the South of France at the end of June 1875, and thereby to have rendered important services by their timely warning.

THE Norwegian Government has taken another step towards discovering the origin and nature of the terrible disease leprosy, which is so common on the west coast of Norway, by despatching Dr. G. A. Hansen, Director of the Leprosy Hospital at Bergen, to North America, for the purpose of inquiring into the heredity of the disease among Scandinavian emigrants to the United States.

SOME interesting statistics concerning the libraries of the United States have been printed in America from advance sheets of the forthcoming Report of the Bureau of Education. There are in the United States 5338 libraries, each with 300 volumes or over. Of these, 2981 have each 1000 volumes or over. Forty-seven have each over 50,000 volumes; and among the forty-seven are the public libraries of Boston, Chicago, and Cincinnati, and the libraries of Harvard, Columbia, Yale, Cornell, and Brown Universities. These forty-seven libraries aggregate 5,026,472 volumes; and the whole list of 5338 libraries aggregates 20,622,076 volumes, or one volume to every three persons in the country. In round numbers the United States has one library to every 10,000 of population, though in many States the proportion is far greater. New Hampshire, for example, has a library to every 2700 persons. Massachusetts and Connecticut furnish a library to every 3134 and 3479 persons respectively. California, Colorado, Wyoming, and Michigan, are well up on the list. Arkansas, which stands lowest, has one library to every 50,158 of population.

SOME time ago we reviewed a little book entitled "A Year with the Birds," by an Oxford Tutor. A second edition has now been issued. The author has added a chapter on the Alpine birds, and has also made a considerable number of additions and corrections in the original chapters.

THE annual general meeting of the Linnean Society of New South Wales took place on January 26. The usual address was delivered by the President, Prof. W. J. Stephens, who presented a general summary of all the scientific work included in the year's Transactions. He also drew attention to the labours of other scientific Societies of Australasia during the preceding year, and concluded with some observations on scientific teaching in general schools.

THE additions to the Zoological Society's Gardens during the past week include a Malayan Bear (*Ursus malayanus*) from Malacca, presented by Mrs. Bingham; a Common Squirrel (*Sciurus vulgaris*), British, presented by Mr. H. B. Meadows; two Tree Pipits (*Anthus arboreus*), British, presented by Mr. W. B. Tegetmeier; two Dwarf Chameleons (*Chamaeleon pumilus*), two Robben Island Snakes (*Coronella phocarum*), a —— Toad (*Bufo angusticeps*) from South Africa, presented by the Rev. G. H. R. Fisk; two Pondicherry Vultures (*Vultur calvus*) from India, two Ocellated Sand Skinks (*Seps ocellatus*), South European, purchased; two Black Lemurs (*Lemur macaco*), a White-fronted Lemur (*Lemur albifrons*), born in the Gardens.

ASTRONOMICAL PHENOMENA FOR THE WEEK 1887 APRIL 3–9

(FOR the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is here employed.)

At Greenwich on April 3

Sun rises, 5h. 33m.; souths, 12h. 3m. 22·6s.; sets, 18h. 34m.; decl. on meridian, 5° 18′ N.: Sidereal Time at Sunset, 7h. 21m.

Moon (Full on April 8) rises, 12h. 29m.; souths, 20h. 12m.; sets, 3h. 44m.*; decl. on meridian, 15° 47′ N.

Planet	Rises	Souths	Sets	Decl on meridian

GEOGRAPHICAL NOTES

THE new number of the *Mittheilungen* of the Vienna Geographical Society contains several letters written by Dr. O. Lenz during his journey from Kasonge, on the Upper Congo, and the Shiré River, to the south of Lake Nyassa (June to December 1886). These letters are, to a large extent, occupied with details of the troubles which Dr. Lenz had with his men. Kasonge is a most unhealthy town. Bohndorf, Lenz's companion, was struck down with fever, and had to be carried most of the way, while small-pox broke out among his men, seriously hampering the proper work of the Expedition. Lenz left Kasonge on June 30, and reached the Island of Kavala, off the west shore of Lake Tanganyika, the head-quarters of Capt. Hore, on August 7. On the route he passed many villages recently built by Zanzibaris, the native population having retired into the forests and mountains. The region is mainly an open table-land, sometimes of a beautiful park-like aspect, and with the river-valleys thickly wooded. As Tanganyika was approached, the plateau rose to a height of 3000 to 4000 feet, with mountains rising from its surface to an equal height. The chief rock was granite, with crystalline slates, and wooded spurs. After staying a few days with Mr. Hore, Dr. Lenz crossed to Ujiji, which he reached on August 15. Here he found himself compelled to give up his proposed journey to Emin Pasha, and in a large boat he and his men sailed down the lake to the south shore, which he reached on September 27. Mr. Hore informed him that the Lukuga River now flows with a strong current out of Lake Tanganyika to the Lualaba. Mr. Hore, who has known the lake for ten years, assured Dr. Lenz that during that time its level has fallen 15 feet, and as the latter sailed down the lake he saw clearly enough the marks of the old shore-lines. With difficulty Dr. Lenz obtained assistance on the inhospitable south shore to continue his journey onwards to Lake Nyassa. This route has been traversed several times, and Dr. Lenz does not in these letters add much to our knowledge. It is a plateau with mountains rising from it to a considerable height, and to the south-west of Lake Tanganyika he came upon the sources of the Chambeze, which, flowing into Lake Bangweolo, may be said to form the remotest sources of the Congo. On October 17 he reached Nkonde, on Lake Nyassa, a station of the African Lakes Company, and thence made his way down the lake and on to the River Shiré, whence his last letter is dated, in December 1886.

IN the same number will be found the conclusion of Herr Glaser's paper on his journeys in South Arabia, in which he gives some important information on the various classes of the population. He speaks in the worst possible terms of the climate of the region: highland and lowland are equally bad, and deadly for Europeans.

THE leading paper in the last number of the *Verhandlungen* of the Berlin Geographical Society is Dr. Wolf's account of his important exploring work on the Sankuru, the great southern tributary of the Congo. This he navigated upwards from the Kassi, exploring its three great sources, the Lomomi, the Lussambo, and the Lubi. It is on the whole a magnificent water-way, its banks in many parts thickly wooded and densely populated. He gives much information concerning the two leading peoples here, the Bakutu and the Baluba, both of them evidently intruders on the Batua, the pygmy people referred to in our last number, the former coming from the north-west and the latter from the south-east. Herr Staudinger adds considerably to our knowledge of the Niger region in his narrative of his journey from Loko, on the Binué, to the kingdoms of Saria, Kano, Sanfarra, Sokoto, and Gando.

HERR FERDINAND SEELAND contributed to a recent meeting of the Austro-German Alpine Club some useful data on the rate of movement of the Pasterz Glacier. On October 3 last he found the glacier entirely free from snow, and he was lucky enough to find six pegs which he inserted in 1882 near the Hofmann Hut straight across the glacier to the base of the Glockner, and also two stones which he laid down in 1884. In the four years 1882–86 the first peg had moved downwards 121·5 m. (*i.e.* at the rate of 3·5 mm. per hour), the second 162 m. (4·6 mm.), the third 175·5 m. (5 mm.), the fourth 192·3 m. (5·5 mm.), the fifth 201·5 m. (5·8 mm.), and the sixth 198·6 m. (5·7 mm.). Of the stones, in the two years one had moved 104·2 m. (5·9 mm.), the other 100·7 m. (5·8 mm.). According to these results (in the direction from the north edge of the glacier towards the centre), the mean rate of movement on a slope of 4 to 5 degrees is 5·23 mm. per hour, or 125·1 mm. per day. Herr Seeland left the pegs and stones where they were, and laid down other marks for future measurements.

LIEUT. WISSMANN, who has already done so much good exploring work in the Congo region, started in November last on a fresh expedition, from Luluaburg, the station on the River Lulua, an affluent of the Kasai. Wissmann goes first to the junction of the Lubi with the Sankuru, the great southern tributary of the Congo. Thence he will endeavour to push northwards and explore the unknown country in which the Lulongo, the Chuapa, and the Lomami take their sources. He will then seek to reach Nyangwé, when he will make up his mind either to proceed northwards to the Muta Nzigé, or south to explore the Lanji, the Lukuga, and the Upper Lualaba.

THE paper at Monday's meeting of the Royal Geographical Society was by Mr. J. T. Wills, on the region between the Nile and the Congo. It was a summary of all that we know of the region, and places us in a position to appreciate the value of any exploring work which may be done by Mr. Stanley. It deals succinctly with all recent explorations of the Upper Nile region, and with the intervening country between that and the Middle Congo. The valuable work of Dr. Junker, as well as that of Emin Pasha, receives special prominence. Mr. Wills rightly dismisses the Shari hypothesis in connexion with the Welle-Makua, and insists on the identity of the Makua and Mobangi. The Mobangi is known to be a waterway not inferior to the main Congo for practical purposes; deep, never less than 600 yards wide, even in February, when the Kuta Makua certainly (and it too apparently) is at its lowest level; and navigable at all times from Stanley Pool 650 miles thence straight north-north-east to lat. 4° 20′ N. beyond the limit which the Congo State, by private treaty with Germany, has placed to its future "sphere of operations," and beyond the limits which the French will probably occupy if they win in their dispute with the Congo State as to which of the two shall not operate in the Mobangi basin. It is then found to turn sharply to the east, flowing from the east through a gap it has cut in a line of quartz and red clay hills 1000 feet high, hills which may be continuation of the hilly watershed between the Makua at Ali Kobo and the sources of the Ngala. One would expects rapids at such a place, but there is only a good current and some awkward rocks; after reconnoitering in a boat, Mr. Grenfell got the *Peace* through easily, in February. Where we know the Kuta Makua next, they are placid and colossal; the Shinko at Marra is still 90 yards wide, 20 to 35 feet deep in October, and only 1980 feet above the sea. The average fall thence to Stanley Pool (1070 feet above the sea) is by this only some 9 inches to the mile, and the main Congo appears to nearly maintain this slope up to Bangala, beyond the Mobangi mouth.

BIOLOGICAL NOTES

INJURIOUS FUNGI IN CALIFORNIA.—The following facts recorded by Prof. W. G. Farlow are not without interest in Europe: *Nicotiana glauca*, abundant in Mexico, attracts attention by its pleasing foliage and graceful habit; it is a native of Buenos Ayres, but is acclimatised in Mexico. Within the last few years it has escaped from cultivation in California, and is now a common weed by the roadsides. At San Diego Prof. Farlow noticed that the leaves were badly attacked by a fungus which formed large, grayish-black spots on both sides of the leaves. Examination proved it to be *Peronospora hyoscyami*, De Bary, which was first found on *Hyoscyamus niger*, L., in Europe, where it does not appear to be at all common. Since it is well known that the species of Peronospora attack different species of flowering plants which belong to the same natural order, it is much to be feared that the disease which now attacks *N. glauca* may sooner or later extend to the cultivated tobacco, which belongs to the same genus. If this were to happen, the injury to the tobacco would be very great, since, by causing large spots on the leaves to rot, they would become worthless for manufacturing purposes. The question of the possible spread of the disease is one of importance, for it would be a very serious thing if it were to reach the great tobacco-growing regions of States like Virginia.

FERTILISATION OF CASSIA MARILANDICA.—The relation of insects to flowers continues to be a question of profound interest, but Mr. Meehan thinks that the dependence of a plant on insect aid is rather an indication that, instead of any material aid to its race being gained, its race is nearly run; he thinks that the opposite assumption has been an injury to the study of the main questions on fertilisation, and that the statements of Darwin and Asa Gray do not warrant the generalisations that have been drawn from them. In *C. marilandica* the phenomena attending pollen-formation are curious and apparently little known. The stamens are arranged in different sets. There are three beneath the pistil—the two lateral ones are very strong and equal the pistil in length, the central one immediately beneath the pistil is as long as those on each side, but more slender. Immediately above the pistil are four stamens, with short stout filaments, the anthers being perfectly formed and nearly as long as in the lower set. Above are three petaloid stamens. All the stamens have long black anthers, full of pollen, but which seems never to burst the anther cases. The only opening is at the apex, and this opening is covered by a membrane—never opening except by insect agency. As soon as the flower expands it is freely visited by humble-bees, and, as their loaded thighs evidence, for the pollen. To collect this they alight on the anthers of the long and lower stamens, as on a platform, make an opening in the apex of each of the four shorter ones, and then rifle them of their contents. A mass of plants containing eighty-eight flower-stems was watched on July 30, and the same lot for an hour on August 6, but no attempt was seen to be made by the bees to get the pollen from the longer anthers, or to use them in any way but as a platform. It would be very difficult for the bees to stand anywhere so as to have power to pierce the apical membranes of the longer stamens. When the flowers matured, and the anthers were ready to fall, they were examined, the four short ones were empty sacs, the three lower ones were full of pollen. These latter served no visible object to the flower or its insect visitors. While, however, no pollen could be detected on the stigmatic surfaces, still three out of every twelve flowers yielded a pod, and panicles of flowers covered so as to prevent egress of insects, neither produced fruit nor did a single anther open at its apex. In this case it would appear as if the fertilisation depended on the accident of the extracted pollen escaping from the insect to the stigma, and yet to an ordinary observer this plant would seem one specially arranged for cross-fertilisation. (Proc. Acad. Nat. Sci. Phil. 1886, p. 314.)

VARIATIONS IN THE NERVE-SUPPLY OF THE LUMBRICALES MUSCLES IN THE HAND AND FOOT, WITH SOME OBSERVATIONS ON THE PERFORATING FLEXORS.—Dr. H. St. John Brooks has lately investigated the subject of the varieties in the nerve-supply of the lumbricales. He finds—(1) Discrepancies in the statements of English and Continental anatomists. All these writers appear to be in error about the normal or commonest arrangement of the nerves to these muscles in the foot, and they appear never to have noticed a *double* supply to the third lumbrical in the hand. (2) Varieties of innervation that the author has observed in man, with an account of the nerve-supply in the orang, gibbon, and macaque monkey. He has discovered nerves entering the deep surface of the second (or indicial) lumbrical muscle in both hand and foot; these nerves, he believes, have never before been described: the latter, however, has been seen by Prof D. J. Cunningham in the foot of a negro, and is recorded by him in his notes (as yet unpublished) of the anatomy of the negro foot. The following statistical table is compiled from the author's notes:—

Table of Variations in the Innervation of Lumbrical Muscles

HAND	Cases
First and second by median; third and fourth by deep ulnar	9
Third by median and deep ulnar (others as before) . .	6
Second and third by deep ulnar	1
First, second, and third by median (deep dissection not carried out)	2
Total	18
FOOT	
First by internal plantar; second, third, and fourth by deep external plantar	8

In the orang, gibbon, and macaque, the second lumbrical of the foot was supplied as in the above table. (3) Prof. Cunningham (*Challenger* Reports, vol. xvi.) has shown that, in Thylacinus and Cuscus, the lumbricals of the manus are all supplied on their superficial surface; a similar arrangement is found in the pes of the fox-bat; here, however, the deep external plantar also furnishes twigs to the two outer lumbricales. (4) It appears probable from these facts that the lumbricals were all originally supplied on their superficial surface: the deep nerve (ulnar in hand, external plantar in foot) is, on this hypothesis, gradually displacing the superficial (median; internal plantar). This invasion of the deep nerve has advanced further (in the case of the lumbricals) in the human foot than in the hand. The reverse is the case with the innervation of the short muscles of the pollex and hallux. (5) There is a general correspondence between the innervation of a particular lumbrical muscle and that belly of the long perforating flexor of which it is a part; this fact is best made out in the case of the first or indicial lumbrical of the hand and the indicial belly of the flexor perforans, which are both supplied by the median: it is also seen in the fourth lumbrical and the belly of the long flexor ending in the tendon to the little finger (both by ulnar); also in the third lumbrical and annular belly (both of which have typically a double nerve-supply). In the foot and leg this part of the investigation presents special difficulties, which have, however, in a measure been overcome by minute dissections of the posterior tibial nerve and its branches, conducted under water. (*Dublin University Reports.*)

ON CERTAIN MODERN DEVELOPMENTS OF GRAHAM'S IDEAS CONCERNING THE CONSTITUTION OF MATTER[1]

I.

THERE is a certain fitness in our selecting this place to do honour to-night to the memory of Thomas Graham. For was in the chemical laboratory of this Institution that Graham carried out, upwards of half a century ago, the experimental investigations which culminated in his memorable discovery of the law connecting the rate of movement of a gas with its density. This law, combined with that of Boyle, which connects the volume of a gas with its pressure, and with the law of Charles, which expresses the relations of the volumes of gases to heat, has done more to give precision to our knowledge of the constitution of matter than all the speculations of twenty centuries of schoolmen.

Graham was made Professor of Chemistry in the Andersonian Institution in 1830, and it was from here that he gave to the world his classical paper "On the Law of the Diffusion of Gases," read before the Royal Society of Edinburgh, December 19, 1831. I am fully conscious that my only claim to be regarded as worthy to pronounce this eulogium of Graham arises from the circumstance that I also have had the good fortune to hold the Lectureship of Chemistry in this place; and with forerunners like Birkbeck, Gregory, and Graham, I may well be proud of an honourable and distinguished ancestry. This association with the Andersonian Institution naturally quickened my interest in Graham and his works, and my frequent opportunities of conversation with the late Dr. James Young, of Kelly, who for so many years was its President, and who was, as we all know, also one of Graham's discoveries, and for a long time, both here and in London, one of his most trusted assistants, enabled me to learn much of Graham's personal character and mode of work. On the occasion of the gift of Brodie's fine statue of Graham to the city by Dr. Young it fell to my lot to prepare the short biographical notice of my distinguished predecessor, which, with other papers relating to the matter, is, I understand, deposited in the archives of your Corporation. And I may be pardoned, perhaps, for recalling with what mingled feelings of pride and trepidation I set myself to the execution of that task.

In the preface to the admirable reprint of Graham's papers which we also owe to the filial piety of Dr. Young, the late Dr. Angus Smith has indicated in precise and even luminous language Graham's position in that chain of thinkers which includes Leucippus, Lucretius, Newton, and Dalton. Indeed, of all Angus Smith's papers with which I am acquainted there is none, to my thinking, more charming than this little introductory essay of a dozen octavo pages, in which, with unwonted perspicacity, he has defined Graham's place in the history of speculative philosophy. Angus Smith has here crystallised out, as it were, the thoughts of a life-time of literary research and meditation. Probably, no man—certainly no contemporary of Graham's—was better fitted by knowledge and by sympathy to form a sound critical estimate of such a position than the biographer of John Dalton. Angus Smith's mind was simply steeped in the old Hellenic philosophy. To him even Kapila was more than a name, and the atomic systems of India matters of more than conjecture or of passing interest. There was much in Smith's intellectual nature to make such inquiries congenial to him. With all his leaning towards objective science he had a Highlander's love of the mystical and a Lowlander's passion for metaphysics. And yet nothing is more admirable than the manner in which, in this essay, these qualities and this wealth of learning are subordinated and held in check, and nothing more striking than the way in which, in a few graphic strokes, done with a master hand, lightly yet firmly, with a consciousness of power and a sense of restraint, Graham's place in the evolution of the atomic philosophy is set forth.

It is here claimed for Graham that he was a true descendant of the early Greeks, and that to him belonged as of right the mantle of Leucippus. Atoms and eternal motion were as much fixed articles of his creed as they were of that of Heraclitus. But with no one of the older Greeks was Graham's thought more in harmony than with that of Leucippus. He, with his wider knowledge of the so-called "elemental" forms of matter, and of the persistency with which the specific properties which we associate with our "elements" are retained, could yet share with the old Greek his conceptions of the essential oneness of matter. It was with Graham, as Smith says of Leucippus, that "the action of the atom as one substance taking various forms by combinations unlimited, was enough to account for all the phenomena of the world. By separation and union, with constant motion, all things could be done."

In one respect Graham's position as an atomist is unique: no man before him had dedicated his life to the study of atoms and atomic motion. These fundamental ideas are intertwined to make up, so to say, the silver thread which runs through the work of forty years. They were the dominant conceptions of his life. Even in his earliest paper, published when he was just twenty-one, in which he treats of the absorption of gases by liquids, we are able to detect in the phraseology employed that his mind had been already permeated by the notion of atomic movement. That he should be familiar, even at this time, with the conception of atoms in the Daltonian sense is hardly surprising when we remember that he had already come under the influence of Thomas Thomson, whose place in the history of science is probably that of the first great exponent of Dalton's theory of chemical combination. But the idea of motion was never with Dalton an integral part of his theory, nor, in so far as it was necessary as serving to explain the phenomena of chemical union, was it held by Thomson. And this is the more remarkable when we remember that Dalton had discovered for himself the fact of the molecular mobility of a gas, and that his first glimpses of the truth of his great law were obtained by the study of chemical combination among gases. Graham was doubtless cognisant, in a general way, of the speculations of the early Greeks, but there is no evidence in any of his writings, nor has anything been preserved in the reminiscences of his friends and contemporaries, to indicate that he was knowingly influenced by them.

This continuity of idea is indeed the most striking characteristic of Graham's labours; all his work seemed to centralise round this fundamental conception of atomic motion. "In all his work," says Smith, "we find him steadily thinking on the ultimate composition of bodies; he searches after it in following the molecules of gases when diffusing; these he watches as they flow into a vacuum or into other gases, and observes carefully as they pass through tubes, noting the effect of weight and of composition upon them in transpiration. He follows them as they enter into liquids and pass out, and as they are absorbed or dissolved by colloid bodies, such as caoutchouc: he attentively inquires if they are absorbed by metals in a similar manner, and finds the remotest analogies, which, by their boldness, compel one to stop reading and to think if they be really possible. He follows gases at last into metallic combination, and the lightest of them all he makes into a compound with one of the heavier metals, chasing it finally through various lurking-places until he brings it into an alloy and the form of a medal, and puts upon it the stamp of the Mint. Indeed he is scarcely satisfied even with this, and he finds in bodies from stellar places—in meteoric iron—this same metallic hydrogenium which he draws out from its long prison in the form of a gas. . . If we examine his work on Salts and on Solutions we have a similar train of thought. One might have slighted the importance which he attached to the water of salts and the temperature at which it was reduced, but in his hands it was a revelation of some of the most mysterious internal phenomena of these bodies.

---

[1] The Triennial "Graham Lecture," given in the Hall of the Andersonian Institution, Glasgow, on March 16, by Prof. T. E. Thorpe, F.R.S.

"A chemist must take great pleasure in following Graham when he seeks the laws of the diffusion of liquids and traces their connections, especially when they lead to such results as he expressed by dialysis, a process founded on a new classification of substances, and promising still the most valuable truths. We see in the inquiry how Graham thought on the internal constitution of bodies, by examining the motion of the parts, and from the most unpromising and hopeless masses under the chemist's hands—amorphous precipitates of alumina or of albumen—brought out analogies which connected them with the most interesting phenomena of organic life. Never has a less brilliant looking series of experiments been made by a chemist, whilst few have been so brilliant in their results or promise more to the inquirer who follows into the wide region opened."

In a short paper entitled "Speculative Ideas respecting the Constitution of Matter," originally published in the Proceedings of the Royal Society for 1863, Graham has left us his Confession of Faith upon the subjects to which he had devoted the whole of a thoughtful life. He conceives that the various kinds of matter now recognised as different elementary substances may possess one and the same ultimate or atomic molecule existing in different conditions of movement. Graham traces the harmony of this hypothesis of the essential unity of matter with the equal action of gravity upon all bodies. He recognises that the numerous and varying properties of the solid and liquid, no less than the few grand and simple features of the gas, may all be dependent upon atomic and molecular mobility. Let us imagine, he says, one kind of substance only to exist—ponderable matter; and further that matter is divisible into ultimate atoms, uniform in size and weight: we shall have one substance and a common atom. With the atom at rest the uniformity of matter would be perfect. But the atom possesses always more or less motion, due, it must be assumed, to a primordial impulse. This motion gives rise to volume. The more rapid the movement the greater the space occupied by the atom, somewhat as the orbit of a planet widens with the degree of projectile velocity. Matter is thus made to differ only in being lighter or denser matter. The specific motion of an atom being inalienable, light matter is no longer convertible into heavy matter. In short, matter of different density forms different substances—different inconvertible elements as they have been considered.

It should be said that Graham uses the terms "atom" and "molecule" in a wider sense than that which the limitations of modern chemistry have imposed upon them, and that he is referring to a lower order of molecules or atoms than those which more immediately relate to gaseous volume. The combining atoms of which he conceives the existence are not the molecules of which the movement is sensibly affected by heat with gaseous expansion as the result. According to Graham, the gaseous molecule must itself be viewed as composed of a group or system of the inferior atoms, following as a unit laws similar to those which regulate its constituent atoms. He is in fact applying to the lower order of atoms ideas suggested by the gaseous molecule, just as views derived from the solar system are extended to the subordinate system of a planet and its satellites.

We cannot as yet fix any limit to this process of molecular division. To Graham the gaseous molecule is a reproduction of the inferior atom on a higher scale. The diffusive molecules, the molecules or systems which are affected by heat, are to be supposed uniform in weight but to vary in velocity of movement in correspondence with their constituent atoms. Hence the molecular volumes of different elementary substances have the same relation to each other as the subordinate atomic volumes of the same substances.

On this basis Graham builds up a conception of chemical combination. He points out, in the first place, that these more and less mobile or light and heavy forms of matter have a singular relation connected with equality of volume. Equal volumes of two of them can coalesce together, unite their movement and form a new atomic group, retaining the whole, the half, or some simple proportion of the original movement and consequent volume.

Chemical combination thus becomes directly an affair of volume and is only indirectly connected with weight. Combining weights are different because the densities, atomic and molecular, are different. The volume of combination is uniform, but the fluids measured vary in density. This fixed combining measure—Graham's *metron* of simple substances—weighs 1 for hydrogen, 16 for oxygen, and so on with the other "elements."

Graham, however, points out that the hypothesis admits of another expression. Just as in the theory of light we have had the alternative hypotheses of emission and undulation, so in molecular mobility the motion may be assumed to reside either in separate atoms and molecules, or in a fluid medium caused to undulate. A special rate of vibration or pulsation originally imparted to a portion of the fluid medium enlivens that portion of matter with an individual existence, and constitutes it a distinct element or substance.

The idea of the essential unity of matter finds its analogy, to Graham's thinking, in the continuity of the so-called physical states of matter. He clearly perceived that there is no real incompatibility in the different states of gas, liquid, and solid. These physical conditions are, indeed, often found together in the same substance. The liquid and the solid conditions supervene, as Graham puts it, upon the gaseous condition rather than supersede it. They do not appear as the extinction or suppression of the gaseous condition, but as something superadded to that condition. Graham conceives that the three conditions (or constitutions) probably always co-exist in every liquid or solid substance, but one predominates over the others, just as the colloidal condition or constitution which intervenes between the liquid and crystalline states extends into both, and probably affects all kinds of solid and liquid matter in a greater or less degree. Hence, to Graham's thinking, the predominance of a certain physical state in a substance appears to be a distinction analogous to those distinctions in natural history which are produced by unequal development. Liquefaction or solidification does not involve the suppression of the atomic or molecular movement but only the restriction of its range.

Such then are Graham's ideas, formulated in 1863, respecting the probable constitution of matter. I have purposely stated them in great detail, and for the most part in Graham's own words. The paper is very short, but it has evidently been put together with great care. It is impossible not to be struck with the evidence it affords of Graham's insight, his grasp of principles and power of co-ordination. Consider, for example, what he says respecting the continuity of the so-called physical states of matter, and bear in mind upon what an extremely small experimental basis it rested at that time. The observations of Caignard Latour were almost forgotten, or at all events their significance was not understood. The classical work of Andrews was not yet published. And yet this work and that of a dozen experimentalists in France, Russia, and Germany, has only served to confirm and expand Graham's fundamental conception. The whole paper shows Graham in a very different light from that in which the student of to-day might be apt to regard him. The greater number of his memoirs are mainly the records of measurements, but Graham was not a great measurer in the sense in which we apply that term to such men as Regnault, Magnus, or Bunsen. Very little of his work was done by his own hands, and it must be confessed that the earlier experimental portion was occasionally intrusted to apparently inexperienced assistants. Graham had, however, the *forscherblick* which characterises the true investigator, and he possessed a really marvellous faculty of sifting out the small grain of fact which often lay hidden beneath a mass of imperfect observation. And yet he was in no hurry to theorise. He patiently added fact to fact, repeating and verifying his observations long after he had got an inkling of the truth towards which they were tending. He laboured like Faraday, *ohne Hast*, *ohne Rast*, and his work is a monument of patient, concentrated thought, and of a singleness of purpose which never swerved.

"Experimentarian philosophers" of Graham's type (to use a phrase which Hobbes of Malmesbury once flung at the progenitors of the Royal Society) have very similar intellectual tendencies. One is insensibly led to compare Graham with the greatest of our English atomists—John Dalton. If you will turn to Dr. Henry's "Life of Dalton," and read the charming analysis of Dalton's mental characteristics, made by one who knew him well and who had studied him carefully, you will find that practically all that is there stated is equally applicable to Graham. Both men were pre-eminently endowed with the faculty of contemplating abstract relations of space and number, and each began his researches with the expectation that all empirical phenomena were to be brought under the control of mathematical laws. Thus Dalton strove to prove that the changes produced in the gaseous and liquid states of matter vary as the square, cube, or some other simple function of the temperature; Graham, in like manner sought to show that the movement of his diffusive molecules, whether in liquids or in gases, was related to some equally simple function of their mass. Henry says of Dalton that "his inmost mental nature, and all its outward manifestations were in the language of the German metaphysicians, emphatically subjective. Thus in special or objective chemistry he has left absolutely no sign of his presence; no great monograph on an individual body and its compounds; no memorable analysis of a substance deemed simple into yet simpler elements; no new element—no Neptune—added to the domain of chemistry." Every word of these sentences could be applied with equal truth to Graham. The tendencies of both men were essentially introspective. Each was capable of the most patient concentrated thought and of steady prolonged attention, wholly abstracted from external objects and events. I have heard the late Dr. Young narrate the most extraordinary instances of Graham's power of mental abstraction. Dalton said of himself that, "If I have succeeded better than many who surround me, it has been chiefly, nay, I may say, almost solely, from unwearied assiduity. It is not so much from any superior genius that one man possesses over another, but more from attention to study and perseverance in the objects before them, that some men rise to greater eminence than others."

It seems like a contradiction in terms when we reflect for a moment upon the characteristic features and tendency of his work, to say that Graham, like Dalton, was utterly devoid of the quality we call imagination. Henry says of Dalton that imagination had absolutely no part in his discoveries; except, perhaps, as enabling him to gaze in mental vision, upon the ultimate atoms of matter, and as shaping forth those pictorial representations of unseen things by which his earliest as well as his latest philosophical speculations were illustrated. Graham would not allow his fancy even that amount of play. Even in the speculative essay from which I have quoted so largely, it seems as if every word had been weighed and every sentence put together with slow laborious thought. This passionless aspect of his work seems to have greatly impressed Angus Smith, himself a man of lively sympathy and of quick susceptibility. "His works," says Smith, "are full of care but not of joy."

(*To be continued.*)

SCIENTIFIC SERIALS

American Journal of Science, March.—On the absolute wave-length of light, by Louis Bell. The experiments here described were undertaken with a view to check the results obtained by C. S. Pierce for Prof. Rowland's great map of the solar spectrum, and to furnish a value of the absolute wave-length as nearly as possible commensurate in accuracy with the micrometrical observations. For the wave-length of D, at 20° C. and 720 mm. pressure, Mr. Bell obtains 5896·08, or *in vacuo* 5897·71, as compared with 5896·22, Rowland's micrometer measure from Pierce's preliminary result, and 5895·89, Thalén's correction of Ångstrom, both in air at ordinary temperature and 760 mm. pressure. But neither of these was corrected for errors in the gratings; hence, obviously, the cause of the discrepancy.—On the relative wave-length of the lines of the solar spectrum, by Prof. Henry A. Rowland. This measurement of the relative wave-lengths of the spectrum and its reduction to absolute wave-lengths by some modern determination has been undertaken in connexion with the photographic map of the solar spectrum on which the author has been engaged for several years, and which is now finished from the extreme ultra-violet wave-length 3200 down to wave-length 5790. Appended are tables of coincidences and of wave lengths of standard lines.—The norites of the "Cortlandt series" on the Hudson River, near Peekskill, New York (continued), by G. H. Williams. Here are studied the mica norites, the augite norite (hyperite), pyroxenite, and the iron ore and emery in the Cortlandt norite. Owing to incipient alteration, easily visible under the microscope, the West-Chester County emery appears to be of less commercial value than that of Asia Minor.—Natural solutions of cinnabar, gold, and associated sulphides, by George F. Becker. In the course of investigations on the geology of the quicksilver deposits of the Pacific slope, the author has made some studies, here detailed, on the question of the state of combination in which quicksilver is dissolved in natural waters. The solubility of zincblende, pyrite (marcasite), copper sulphides, gold and other associates of cinnabar, is incidentally examined, the quantitative analysis involved in the process being made by Dr. W. H. Melville.—Fluviatile swamps of New England, by N. S. Shaler. In examining the fresh-water swamps of this region, the author has carefully studied the geographical distribution of those formed along the banks of rivers. Although the inquiry is mainly limited to the post-glacial changes in the valleys trending northwards, much light is incidentally thrown on the pre-glacial altitude of the continent. It is made evident that these valleys could not have been excavated by streams of their present slope; hence the inference that the descent of the northward flowing rivers must have been more rapid in pre-glacial times than at present; in other words, this part of the continent was at that time relatively less elevated in its northern parts than it is at present.—On the Mazapil meteoric-iron which fell on November 27, 1885, by William Earl Hidden.—On observations of the eclipse of August 18, 1887, in connexion with the electric telegraph, by Prof. David P. Todd. Referring to his remarks in the Proceedings of the American Academy of Arts and Sciences for 1881, p. 359, the author points out how the proposed method of telegraphic transmission of important observations might be adopted during the eclipse of August 18 next.—On two new meteorites from Carroll County, Kentucky, and Catorze, Mexico, by George F. Kunz. The Kentucky iron has some ethnological interest in connexion with the ornaments of meteoric iron occurring in the mounds of the Little Miami Valley, Ohio, all apparently belonging to one and the same meteoric fall. The Catorze mass, weighing 92 pounds, was found near Catorze, San Luis, Potosi, in 1885. It is one of the caillite group of Stanislas Meunier, and shows the Widmanstatten lines very finely. Analysis: Fe 90·09; Ni and Co 9·07; P 0·24; with specific gravity 7·509.

Rivista Scientifico-Industriale, February.—On the cause of the electric discharge accompanying thunderstorms, by Prof. G Guglielmo. The views of Ermann and Peltier are here subjected to close scrutiny, and shown to be inadequate to account for these electric phenomena.—On the variations in the electric resistance of antimony and cobalt in the magnetic field, by Dr. G. Faè. The author's researches show that, apart from the intensity of the observed effects, antimony behaves in the way determined by Righi for bismuth, and cobalt in the way determined by Thomson for iron and nickel.

Rendiconti del Reale Istituto Lombardo, February.—Summary of the meteorological observations recorded in the Brera Observatory, Milan, during the year 1886, by E. Pini. The daily, monthly, and annual means are tabulated for the atmospheric pressure, temperature, rainfall, velocity, and direction of the winds throughout the year.—Meteorological observations for the month of January, 1887, at the same Observatory.

Royal Society, March 10.—"Note on Induction Coils or 'Transformers.'" By John Hopkinson, M.A., D.Sc., F.R.S.

"Note on the Theory of the Alternate Current Dynamo." By John Hopkinson, M.A., D.Sc., F.R.S.

March 17.—"The Embryology of Monotremata and Marsupialia." Part I. By W. H. Caldwell, M.A., Fellow of Gonville and Caius College, Cambridge. Communicated by Prof. M. Foster, Sec. R.S. (Abstract.[1])

(1) *The Egg-membranes.*—In Monotremata, in very young ova, a fine membrane exists between the single row of follicular cells and the substance of the ovum. This membrane, which I will call *the vitelline membrane*, at first increases in thickness with the growth of the ovum, and through it pass numerous fine protoplasmic processes connecting the protoplasm of the follicular cells with that of the ovum, and serving to conduct food granules, which, appearing in the neighbourhood of the nuclei of the cells, travel thence to the ovum; food granules also appear in the neighbourhood of the germinal vesicle, and travel away from it: hence the horseshoe-shape of the yolk-mass as seen in section.

---

[1] The author being at the present time in Australia and so unable to correct the proof of this abstract, I have undertaken this duty. In doing so I have ventured, for the sake of what appeared to be increased clearness, to introduce into § 1 some modifications of the author's manuscript, being guided therein by the author's more detailed account given in the fuller paper.—M. Foster, Sec. R.S.

The time during which food granules are thus passing from the follicular cells to the ovum may be called "the yolk forming period."

It is succeeded by a period during which the vitelline membrane again becomes thin, the follicular cells are reduced to a single layer, and the cells are very thin and flat. This period may be called the "absorption of fluid period," since during it the ovum absorbs large quantities of fluid through the thin vitelline membrane and single layer of thin follicular cells, and thereby increases largely in size.

This is in turn succeeded by a third period, during which the follicular cells again become active, multiply, increase greatly in size, and give rise between themselves and the vitelline membrane to a deeply standing homogeneous layer, which I will call *the chorion*. This period may hence be called "the chorion forming period." All these three periods are gone through while the ovum is still in the follicle.

Upon the bursting of the follicle and the reception of the ovum in the Fallopian tube, a few of the follicular cells remain attached to the chorion; the majority are left behind within the burst follicle.

During the passage along the Fallopian tube, the vitelline membrane again increases in thickness, and the chorion, also increasing in thickness, absorbs fluid and becomes *the albumen layer*. Outside this now appears a new structure, *the shell* or shell-membrane, of tough parchment-like consistency,[1] not staining with reagents. I have not yet traced the deposition of the shell to the activity of any special glands; but I can say that the shell-membrane does not increase at the expense of the chorion or albumen layer.

After reaching the uterus both vitelline membrane and shell-membrane increase in thickness, but the albumen layer diminishes and disappears, serving apparently for the nutrition of the ovum. Immediately beneath the vitelline membrane a new layer is now seen in hardened preparations; but it may be shown that this layer is really fluid, yielding a coagulum which stains deeply with reagents, the fluid being apparently derived, through the membranes, from the uterine glands.

In Marsupialia the history of the vitelline membrane, save that "the yolk forming period" is not marked off from the "absorption of fluid" period, is similar to that in Monotremata. I have not been able to trace the beginning of the "chorion" while the ovum is still in the ovary, in Marsupialia; but in an ovum of Phascolarctos from the uterus, I found a chorion like that of Monotremata, and surrounded moreover by a thin transparent membrane—a *shell-membrane*. Within the uterus the chorion, increasing in thickness, becomes transformed into an albumen layer, and is eventually absorbed, passing through the vitelline membrane to nourish the ovum, so that eventually the vitelline membrane comes to be close to the shell.

As in Monotremata, a coagulable, and, when coagulated, deeply staining fluid makes its appearance between the vitelline membrane and ovum (blastoderm).

The shell-membrane persists until the developing ovum becomes fixed to the walls of the uterus, after which it disappears.

The paper then compares the egg-membranes just described with those of Placentalia, and those of Vertebrata generally.

(2) *Segmentation.*—The telolecithal ova of Monotremata and Marsupialia go through a partial segmentation. The ova of Placentalia segment completely, but the resulting blastodermic vesicle is identical with that produced by partial segmentation in Monotremata and Marsupialia.

In Monotremata there is a posterior lip to the blastopore similar to that of Elasmobranchii. The epiblast grows in so rapidly from the sides, that a primitive streak region is formed in front of the posterior lip long before the epiblast has inclosed the yolk. This uninclosed area in front of the primitive streak probably includes a region where the hypoblast (yolk) has secondarily broken through the epiblast. The existence of such a region would hide the position of the anterior lip of the blastopore. The circumference of the circle made up by the larger arc of the edge of the blastoderm on the yolk, and the smaller arc of the posterior lip of the blastopore, is a measure of the quantity of yolk in a meroblastic ovum.

In Marsupialia the epiblastic growth incloses the hypoblast at a very early age, except over a narrow slit in front of the posterior lip of the blastopore. This slit corresponds to the area inclosed by the circle described above in a meroblastic egg. The primitive streak is not conspicuous at an early age because of the large size of the cells. No hypoblast projects through the epiblast in front of the primitive streak region. I would explain the segmentation and the gastrula of Placentalia in the same way. Balfour's objection ("Comp. Embryol." vol. ii. p. 187) to Van Beneden's original comparison of the blastopore of the rabbit with that of a frog, is explained away by the presence of a posterior lip to the blastopore in Marsupialia. My explanation postulates the existence of a similar structure in the rabbit. The blastopore of the rabbit corresponds therefore to the whole area marked out by the growing epiblast and the posterior lip of the blastopore, before the closing of the primitive streak region, or to this area minus the secondary extension, caused by the projecting yolk, in Monotremata.

Linnean Society, March 17.—Mr. W. Carruthers, F.R.S., President, in the chair.—A recommendation of the Council to present to the British Museum, Kew, and the Oxford Botanical Gardens, the Society's carpological collection was submitted to the Fellows, but not approved by them.—Mr. C. B. Clarke, F.R.S., was elected into the Council in the place of Dr. H. Trimen, who resigned.—Mr. A. O. Walker read a paper on the Crustacea of Singapore. These were collected by Surg.-Major Archer during 1879–83. The species were chiefly dredged in 15–20 fathoms, or got on shallow banks. A full list is given of all the forms identified, and several new species are described. Among these are: *Doclea tetraptera, Xanthe scaberrimus, Maii miersi*, and *Caphyra archeri*.—A paper was read by Dr. Geo. King, on the genus *Ficus*, with special reference to the Indo-Chinese species. The genus *Ficus* was founded by Linnæus, and included seven species ("Species Plantarum," 1st ed.) Later editions contained 118 species. Blume described 93 Malayan figs, and Roxburgh 55 Indian species. In the "Hortus Cliffortianus" Linnæus clearly comprehended the difference of the sexes, *i.e.*, Caprifig = male, the so-called Fig = female, and *Erinosyce* = hermaphrodite. Vahl seems to have misunderstood the arrangement of the sexes, and Blume apparently followed him. Roxburgh is the first writer who examined minutely the florets of nearly the whole of the species, finding two androgynous and the majority monandrous. Later on Gasparini and Miquel each made a careful study of the flowers of the genus, and separately gave different classifications of the group. Miquel subsequently altered his arrangement, making divisions into six sub-genera, while enumerating 405 Old World, 128 American, and twenty-two species of doubtful nativity. In the "Genera Plantarum" of Bentham and Hooker four of Miquel's sub-genera are admitted, a fifth considered doubtful, and a sixth rejected. These authors regarded Miquel's divisions as too loosely defined, and recommended a re-working of the group. Dr. King goes into a lengthened description of the structural peculiarities of the flowers of the genus *Ficus*. He specifies (1) male, (2) pseudo-hermaphrodite, (3) neuter, and (4) female fertile flowers. Besides these, he states that there occurs in all the species of *Ficus* a set of flowers originally named by himself "*insect-attacked-females*," but for which he has adopted Count Solms-Laubach's term "*gall-flowers*" (*Bot. Zeit.* 1885); the latter botanist having anticipated him in publication, though King's researches had been commenced earlier. King enters into the question of these gall-flowers, stating that, in the majority, the pupa of an insect is present, and this pupa can usually be seen through the coats of the ovary. The pupa when perfected escapes into the cavity of the receptacle by cutting its way through or by bursting these coats; and fully-developed winged insects are often to be found in considerable numbers in the cavity of the fig. The opening through which each insect has escaped from the ovary in which it has been developed is afterwards clearly visible. The pupa of the insect must become encysted in the ovary of the gall-flower at a very early period, for about the time at which the imago is escaping from the ovary the pollen of the anthers of the male flower is only beginning to shed. Now, there is nothing in itself remarkable in the mere occurrence in the genus of numerous flowers having the general form of females, which yet by reason of certain peculiarities in their structure are incapable of fertilisation by pollen practically barren; while at the same time their structural defects fit them for becoming the nidus for the larvæ of special insects. But, when the manner in which these malformed female flowers are disposed in the receptacle is inquired into, it becomes clear that through the interposition of insects these malformed female flowers may play a most important part in the life-history of many species of the genus *Ficus*. Thus from the peculiarities in the structure and arrangement of the flowers, Dr. King is of opinion that the evolutionary history of the genus *Ficus* may be traced. On data derived therefrom he arranges the Indo-Malayan species into two great groups, the second of these being again divided into three subsidiary sub-groups as follows:—

---

[1] In the laid egg of Echidna I have not detected calcic salts, but that of Ornithorhynchus gives rise to gas when treated with dilute acid.

Ficus, Linn.	Group I. Pseudo-hermaphrodite.			Palæomorphe
	Group II. Unisexual	Sect. 1		Urostigma
		Sect. 2		Synœcia
		Sect. 3	A	Sycidium Covellia
			B	Eusyce Neomorphe

Physical Society, March 12.—Prof. G. Carey Foster, Vice-President, in the chair.—Mr. Shelford Bidwell described some experiments which seem to show that the electrical resistance of suspended copper and iron wires, alters with the direction of the testing current. The apparatus used consisted of a metre bridge with coils of 100 ohms in the gaps adjoining the standard wire, the other two arms being two suspended wires united at the top, to which point one terminal of the galvanometer was joined. A commutator placed in the battery circuit served to reverse the testing current. When a wire is suspended vertically the stress increases from below upwards, and the author believes the observed effects to be due to the absorption of heat by the current as it passes from a stretched towards an unstretched part of a copper wire, and the evolution of heat when it passes from an unstretched towards a stretched part. As the apparatus was arranged the current passed up one side and down the other, heating the one and cooling the other, thus disturbing the position of balance. If iron wires were used the heating and cooling effects were reversed. Prof. S. P. Thompson suggested loading the wires at different points in order to vary the stress without using such long wires, and Mr. C. V. Boys thought still shorter wires could be used by joining the ends to a revolving spindle and stretching them by centrifugal force.—On a lecture experiment in self-induction, by Mr. Shelford Bidwell. A telephone is placed in series with the secondary coil of an induction coil and another coil whose self-induction can be raised by inserting a core of iron wires, or another coil, or both. The effect of introducing the iron core is very marked, reducing the sound enormously. If a coil of wire containing an iron core be inserted, the effect of short-circuiting the coil is to increase the sound in the telephone. The same author also described and showed an experiment due to Dr. Fleming, in which a disk of copper inclined at an angle of 45° to the axis of a coil of wire and suspended bifilarly, is deflected by passing an undulatory current round the coil. In explanation of the former experiment, Dr. Fleming wrote down the formulæ for the effective resistance and self-induction of a circuit near another closed circuit, which show that the former is greater and the latter less for undulatory than for steady currents. He had not arrived at any satisfactory explanation of the deflection of the copper disk. Prof. Ayrton exhibited a tuning-fork worked electrically, in which the pitch could be varied by altering the self-induction of the circuit, or by varying the position of the make-and-break screw. Mr. C. V. Boys referred to his experiments, published in 1884, on the impulse given to metal disks suspended in a magnetic field whose strength is suddenly changed, as being of a similar character to that described by Mr. Bidwell, and suggested the use of aluminium instead of copper in future experiments, owing to its conductivity for the same weight being greater. Prof. Thompson said he had recently used a similar apparatus to that described by Mr. Bidwell as an illustration of the effect of self-induction, and pointed out the uses of self- and mutual-induction in multiplex telegraphy and telephony. As an explanation of the deflection of the copper disk by alternating currents, Prof. Foster thought it possibly due to its initial position being that of maximum sensibility, and therefore each impulse had less effect than the preceding one. Mr. W. M. Mordey mentioned a simple arrangement for varying self-induction used by Mr. Ferranti to control the power of incandescent lamps worked by alternating currents, and Prof. Ayrton described a closed magnetic circuit of great self-induction, used to protect voltmeters on the telpher line at Glynde from disastrous inductive effects produced by breaking the locomotive circuit. Referring to tuning-forks, Mr. Bosanquet thought some self-induction was necessary in order that the current should act to the best advantage in attracting the prongs at the proper instant. Further remarks were made by Mr. Boys and Prof. Perry.—On a lecture experiment to show that capacity varies inversely as the thickness of the dielectric, by Profs. W. E. Ayrton and John Perry. The authors consider it easy for students to see that, other things remaining constant, capacity is proportional to area. Taking this as proved, a condenser is arranged such that the area A of the insulated inner coating varies as the thickness t of the dielectric, and the potential difference between the coatings is found by experiment to be constant. Then since capacity $= \frac{\text{quantity}}{\text{potential}}$, and both the latter being constant, therefore the capacity of the condenser is constant. But by the construction of the apparatus $\frac{A}{t}$ is constant, and it is assumed that capacity varies as A, therefore capacity must vary inversely as t.—Note on magnetic resistance, by the same authors. Two iron rings about 6 inches diameter, made from the same bar of best Swedish iron about half an inch in diameter, were wound with insulated wire in two halves, so that a current could be sent round either or both halves, and the resulting induction measured by the throw of a ballistic galvanometer placed in series with a few convolutions of wire wound round the outside of the main winding. One of the rings was continuous, and the other had a small air space of about 0·8 mm. in a plane perpendicular to that of the ring and passing through its axis, as if the ring had been cut by a saw. The primary object of the experiments, which were made by Messrs. Aldworth, Dykes, Lamb, Robertson, and Zingler, of the Central Institution, was to determine whether there was any appreciable "surface magnetic resistance." The results do not show any such resistance, and the relative resistance of air and iron as calculated from the unsaturated parts are about as 1200 to 1, a number agreeing fairly well with those obtained by other experimenters. From this the authors conclude that for small distances magnetic resistance of air is proportional to length. When the magnetising current was passed round the one half of the divided ring on which the test coil was wound, a greater induction could be obtained than by any other way of magnetising, and this the authors do not attempt to explain. Mr. Bosanquet said he had always found greater inductions obtainable in the middle of bar electro-magnets or open magnetic circuits, than could be produced in closed magnetic circuits, and thought the above observations confirmed his own results. A discussion followed in which Mr. C. V. Boys, Mr. W. M. Mordey, Mr. Bosanquet, and Prof. Perry took part.—On account of the late hour the reading of a note on dynamo machines and motors, by Profs. Ayrton and Perry, was postponed till the next meeting.

Zoological Society, March 15.—Dr. St. George Mivart, F.R.S., Vice-President, in the chair.—The Secretary read a report on the additions that had been made to the Society's menagerie during the month of February 1887.—Mr. Howard Saunders exhibited a young male Harlequin Duck (*Cosmonetta histrionica*), shot off the coast of Northumberland on December 2 last, and remarked that it was the second authentic British-killed specimen in existence.—Mr. Oldfield Thomas read a paper on the Bats collected by Mr. C. M. Woodford in the Solomon Islands.—A communication was read from Mr. W. R. Ogilvie Grant, containing an account of the birds collected by Mr. C. M. Woodford at Faura and Shortland Islands, in the Solomon Archipelago, and in other localities of the group.—A communication was read from Mr. G. A. Boulenger, containing a second contribution to the herpetology of the Solomon Islands.—Mr. Oldfield Thomas read a paper describing the milk-dentition of the Koala (*Phascolarctos cinereus*), which was shown to be in the same state of reduction as had been described by Prof. Flower in the case of the Thylacine.—A second communication from Mr. Boulenger contained a description of a new Gecko of the genus *Chondrodactylus* from the Kalahari Desert, South Africa, based on a specimen which had been presented to the Natural History Museum by Mr. J. Jenner Weir. The author proposed to call it *C. weiri*.

Geological Society, March 9.—Prof. J. W. Judd, F.R.S. President, in the chair.—The following communications were read:—On *Chondrosteus acipenseroides*, Ag., by Mr. James W. Davis.—On *Aristosuchus pusillus*, Ow., being further notes on the fossils described by Sir R. Owen as *Poikilopleuron pusillus*, Ow.; on *Patricosaurus merocratus*, Seeley, a lizard from the Cambridge Greensand, preserved in the Woodwardian Museum of the University of Cambridge; on *Heterosuchus valdensis*, Seeley, a procœlian crocodile from the Hastings Sands of

Hastings; on a sacrum, apparently indicating a new type of bird (*Ornithodesmus cluniculus*, Seeley), from the Wealden of Brook, by Prof. H. G. Seeley, F.R.S. In the last paper, after some remarks on the characters of the sacrum in birds, Ornithosauria, and Dinosauria, the author proceeded to describe a sacrum composed of six vertebræ in the Fox Collection, now at the British Museum, and then to compare the fossil with the corresponding bones of the three groups named. The resemblance to the Dinosaurian and Ornithosaurian sacral vertebræ was less than those which connected the fossil with birds. From the latter it was distinguished by the smaller number of vertebræ in the sacrum, the absence of sacral recesses for the lobes of the kidneys, and the form of the articular face of the first sacral vertebra. But the small number of sacral vertebræ in *Archæopteryx*, the want of renal recesses in *Ichthyornis*, and the characters of the articulation in the Solan goose showed that these differences were not essential; and the author concluded that the fossil belonged to a true bird, but that it formed a link with lower forms, and approximated more to Dinosaurs than did any other Avian type hitherto described.

Chemical Society, March 17.—Dr. Hugo Muller, F.R.S., President, in the chair.—The following papers were read:—The action of heat on nitrogen peroxide, by Dr. A. Richardson.—Supersaturation of salt solutions, by Dr. W. W. J. Nicol. This paper contains an account of experiments on the physical constants of supersaturated and dilute salt solutions. The solutions were examined in two ways: (1) concentration constant and temperature varying; (2) temperature constant and concentration varying; in this way it was possible to pass from dilute to supersaturated solutions, and to examine the change in the various physical constants. The electric conductivity, specific viscosity and rate of expansion were examined by the first method. The specific viscosity and density by the second. In every case it was found that the curve corresponding to the non-saturated solutions was perfectly continuous with that for the supersaturated solutions. From this the author concludes that the constitution of dilute, saturated, and supersaturated solutions is the same. Supersaturation is explained by the hypothesis that the substance in solution is not the same as that which crystallises out. A supersaturated solution of sodium thiosulphate deposited crystals of the composition $Na_2S_2O_3,H_2O$ when evaporated *in vacuo*, showing that the solution does not contain the pentahydrate. The author believes that the salt in solution is combined with the whole of the water, an opinion based on his experiments on vapour-pressures and molecular volumes. Colour changes in solution are not, he believes, due to hydration, but to rearrangements of the salt molecule similar to that which occurs in the case of chromium sulphate. Dr. Nicol's views were criticised by Mr. Pickering and Dr. Armstrong.—The formation of γ-naphthalenesulphonic acid by means of sulphuric anhydride and on γ-dihydroxynaphthalene, by Dr. Henry E. Armstrong and Mr. W. P. Wynne.—α-Cyanonapthalenesulphonic acid, by Dr. Henry E. Armstrong and Mr. S. Williamson.—Addendum to paper entitled an explanation of the laws which govern substitution in the case of benzenoid compounds, by Dr. Henry E. Armstrong.—The transformation of citric acid into pyridine-derivatives, and on the constitution of pyridine, by Dr. S. Ruhemann.—Silver containing bismuth, by Mr. William Gowland.

Royal Meteorological Society, March 16.—Mr. W. Ellis, President, in the chair.—The following papers were read:—Notes on taking meteorological observations on board ship, by Capt. D. W. Barker. The author makes various suggestions as to the placing of meteorological instruments on board ship with the view of securing uniformity.—Marine temperature observations, by Dr. H. R. Mill. After briefly sketching the principal historical methods of observing temperature beneath the surface of the water, Dr Mill discussed in some detail the relative merits and defects of the two instruments now in common use for this purpose. The self-registering maximum and minimum thermometer on Six's principle, even with the addition of an outer bulb to protect it from pressure, has certain inherent defects. It merely shows the highest and lowest temperatures passed through, the indices are liable to be shaken from their proper position, and it requires long immersion in order to attain the temperature of its surroundings. Mr. J. Y. Buchanan has shown how, by the use of mercury and water piezometers, the actual temperature at a given point may be obtained, no matter how the temperature between that point and the surface may vary. Such instruments have not been much used, and now a modification of the mercurial outflow thermometer, patented by Messrs. Negretti and Zambra as the "standard deep-sea thermometer," is largely used. When fitted in a frame which admits of the thermometer registering at a precisely known depth, admirable results are obtained by it. The manner of using these thermometers in the Scottish frame and of conducting temperature trips in comparatively shallow water was described; and the best ways of recording the observations and elaborating the results were alluded to; the work of the Scottish Marine Station on the Clyde sea area being taken as an illustration. The importance of marine temperature observations as bearing on submarine geography, on navigation, on the distribution of animal life, and consequently on fisheries, was alluded to. The paper was illustrated by diagrams, and by the exhibition of the apparatus which was described.—After the reading of these papers the meeting was adjourned in order to afford the Fellows an opportunity of inspecting the Exhibition of Marine Meteorological Instruments and Apparatus which has been organised under the auspices of the Society.

Victoria Institute, March 7.—The Rev. Dr. Walker read a paper on insect life in the East, in which he gave a full report of his entomological researches in Egypt and the East, and drew special attention to the very great number of British varieties that he had captured in various parts of the world. During the discussion, Dr. Sydney Klein remarked on the value to science of Dr. Walker's labours, and, in regard to insect life in the East at night, said that when passing a night among the ruins of Ephesus he found its superabundance manifested by the actual roar of chirps, scrapings, rattles, hummings, and cries from the country round, quite equalling his experience in the woods of Central America. Mr. Hastings C. Dent gave an account of his observations in South America and elsewhere.

MANCHESTER

Literary and Philosophical Society, January 17.—Prof. W. C. Williamson, F.R.S., in the chair.—Mr. Henry Hyde exhibited a leaf of *Bryophyllum calycinum*, with young plants growing out of the margin.—Dr. Alex. Hodgkinson read a paper on cavities in minerals containing fluid, with vacuoles in motion, and other inclosures.—Prof. W. C. Williamson, F.R.S., gave a practical demonstration by means of sections, shown by the oxy-hydrogen camera, of the structure and development of young roots. Beginning with those of the maize as they appear within the seed, Prof. Williamson exhibited and explained those of the vine, of the bean, of the crown imperial, and of the several species of cycads, illustrating the changes which roots undergo between the uniform structure seen near the root or tip, to their more advanced condition, as seen first in the roots of endogenous plants, and afterwards in the more complicated ones of exogens.

PARIS

Academy of Sciences, March 21.—M. Janssen, President, in the chair.—On the movement of a solid in a liquid, by M. Halphen. A theoretical demonstration is given of the general proposition that this movement consists of (1) a uniform helicoidal motion round a fixed axis in space; (2) a uniform rotation round a fixed axis in the solid; (3) a periodical movement.—On the great atmospheric movements in connexion with MM. Schwedoff, Colladon, and Lasne's cyclonic theories, by M. Faye. The paper is devoted to a refutation of these various theories, which are stated to be mainly due to the confusion caused by failing to distinguish between movements produced artificially in the air or water by a simple rotatory action, and the natural cyclones, tornadoes, waterspouts, &c.; the two orders of phenomena having only an apparent relation to each other.—Some observations and reflections on the earthquake of February 23 at Antibes, by M. Ch. Naudin. At this point of the coast the sea suddenly retired about 3 feet, soon returning with considerable velocity to its normal level. This and the associated phenomena are attributed, not to any volcanic action or to the gases confined in vast subterranean cavities, but to the resistance offered by certain parts of the terrestrial crust to the electricity generated in the globe itself. It is pointed out that these disturbances occur always in districts destitute of forest growths which might serve to discharge the atmospheric electricity, and on this is founded a fresh argument for replanting lands that have become disafforested.—On the red fluorescence of alumina, by M. Lecoq de Boisbaudran. Some experiments are described leading to the inference that this fluorescence is due to the presence of

chromium in ordinary alumina, and cannot b

earth itself.—Earthquakes in con

M. F. A. Forel. It is suggested that the series of slight vibrations almost invariably following the first great shocks may tend to cause the escape of fire-damp in mines, and that the precautions against this danger should consequently be redoubled in mining districts within the range of the general disturbance.—On a possible cause of the earthquakes of 1755, 1884, and 1887, by M. A. Blavier. An attempt is made to associate these occurrences with an abnormal accumulation of ice in the Polar waters, causing a deflection of the Rennel branch of the Gulf Stream, attended by great climatic changes and a slight disturbance of equilibrium in the submarine bed, followed by a possible local fracture along the line of least resistance. The in-rush of cold oceanic waters would appear to be indicated by the disappearance of the sardines from the West Coast of Europe in the years in question.—On the employment of gas as a constant source in experiments on radiation, by M. Edouard Branly. In this communication a comparative study is made of the moderator lamp and gas jet, as two sources of mean temperature in these experiments.—On the tartrate of antimony, by M. Guntz. A process is described for preparing in the pure state the acid tartrate of antimony, which Peligot obtains by alcoholic precipitation of a concentrated solution of the oxide of antimony in tartaric acid.—On the presence and quantitative analysis of alumina in wine and the grape, by M. L. L'Hote. The results are given of experiments made to determine the presence in appreciable quantities of antimony in Burgundy, Roussillon, and some other red wines.—Note on some new syntheses in the fatty series by means of the chloride of aluminium, by M. Alphonse Combes.—On the microbe of yellow fever and its attenuation, second note, by MM. Domingos Freire, Paul Gibier, and C. Rebourgeon. In continuation of their studies on this microbe, discovered by them in 1884, the authors describe a process by means of which the virus may be attenuated and converted into a prophylactic vaccine.—Calorimetric studies on sick children, by M. P. Langlois. The experiments here described show that in chronic disorders with hypothermy there is a diminution of caloric, which increases in maladies with hyperthermy.—On certain characteristics of the pulse in morphiomaniacs, by Messrs. B. Ball and O. Jennings. The observations here illustrated by sygmographic tracings serve both to detect the practice in patients secretly addicted to the taking of morphia and to remove the craving for intermittent doses.—Mineralogical study of the Fort Duncan meteoric iron recently presented to the Paris Natural History Museum, by M. Stanislas Meunier. The analysis of this specimen, found in 1882 near Fort Duncan Maverick County, Texas, shows a remarkable resemblance to the mass which fell at Braunau, Bohemia, on July 14, 1847. It yielded: iron, 92·02; nickel, with traces of cobalt, 6·10; residuum, 1·80; density 7·699.

STOCKHOLM

Royal Academy of Sciences, February 9.—The following papers were accepted for insertion in the Proceedings of the Academy:—On the so-called anomalous dispersion, by the late Colonel C. E. af Klercker. On benzol and toluol monosulcombinations, by Dr. Mats Weibull.—The Lettersted Prize for 1887 for the best original scientific work was awarded to Prof F. A. Smitt for his "Critical Index of the *Salmonidæ* in the National Museum," whilst the amount of the same legacy for special scientific work was awarded to Prof. A. G. Nathorst for his researches on the Tertiary flora of Japan.—The Secretary announced that the Proceedings of the Academy for 1886 were completed, and that the first part ("Aurores boréales") of Series II. of the work "Observations faites au Cap Thordsen, Spitzberg, par l'Expédition Suédoise," published at the expense of the Academy, was issued.—The following two papers were also presented by Prof. Berlin:—On six isomeric acids of toluol disulphone, by Dr. P. Klason. On the substitution of the amido group in aromatic combinations for hydrothion as well as oxysulphuryl by means of diazo combinations, by the same.—Prof. Edlund advanced a strictly mathematical demonstration showing the correctness of his theory regarding unipolar induction.—Prof. Gyldén presented the following papers:—Untersuchungen uber einen speciellen Fall des Problems der drei Korper, founded on studies at the Stockholm Observatory, by Dr. P. Harzer, of St. Petersburg. On the absolute correctness of terms of expression employed by Prof. Gyldén in order to solve the problems of three bodies, by himself, which paper will shortly appear in the *Acta Mathematica*.—Prof. Smitt nnounced the appearance of a new edition of the illustrated viens Fiskar" ("The Fishes of Scandinavia"), in of original drawings by Herr W. von Wright, belonging to the Academy, which have never been published before. He also presented the first report of the Ornithological Committee appointed by the Academy.—Prof. Mittag-Leffler presented the following papers:—On convergents to definite integrals, by Herr C. B. S. Cavallin. On a treatise by Ascoli relating to the integration of the differential equation $D^2u = 0$ for a given Riemann surface, by Dr. G. Enestrom. Integration der differential Gleichung $D^2u = 0$ in einen beliebigen Riemannischen Fläche, by Prof. Giulio Ascoli, of Milan.—The Secretary presented the following papers for insertion in the Proceedings:—On the influence of chlorium on α-acetic naphthalid, by Prof. Cleve. On naphthalid acids, by Dr. A. G. Ekstrand. On α- and β-naphthamidoxim, by the same. On the resin acids in galipot, by Dr. A. Westerberg. On pteropods in the Zoological Museum of the Upsala University, collected by Capt. G. von Scheele, classified by Dr. H. Munthe. Notes on Permian fossils from Spitzbergen, by Prof B. Lundgren. Einfluss der Neutralsalze auf die Reactionsgeschwindikeit der Verseifung von Actylacetat, by Dr. S. Arrhenius.

A NATURALIST IN SOUTH AMERICA

Notes of a Naturalist in South America. By John Ball, F.R.S., M.R.I.A., &c. (London: Kegan Paul, Trench, and Co., 1887.)

I.

BY this unpretending little volume its author has opened up to view a new avenue to knowledge—a royal road, in short, to anyone as competent as he has shown himself to be to take advantage of all that it offers to an intelligent traveller with his eyes and ears open. Its contents are a rich collection of facts and thoughts, chiefly botanical, meteorological, and geographical, acquired during a five months' voyage over 18,400 miles of ocean, and embracing 100° of latitude, during which the author passed only seventy days on dry land; and they are laid before the reader in a style which is as attractive as instructive.

In the preface Mr. Ball says of his voyage:—"A tour round the South American continent, which was completed in so short a time as five months, may not appear to deserve any special record; yet I am led to hope that this little book may induce others to visit a region so abounding in sources of enjoyment and interest. There is no part of the world where a traveller can view so many varied and impressive aspects of Nature, whilst he whose attention is mainly given to the progress and development of the social condition of mankind will find in the condition of the numerous States of the continent, and the manners and habits of the many different races that inhabit it, abundant material to engage his attention and excite his interest." Mr. Ball adds that, though the aim of his journey was mainly to see Nature in aspects new to him, he, as an unprejudiced visitor, gives also his impressions as to the social and political condition of the different regions which he visited. With these impressions we need not concern ourselves, though we may say that they seem to us to be both just and liberal.

Leaving England in March 1882 as a passenger on board a West Indian mail-steamer, Mr. Ball found that the passage across the Atlantic offered nothing of unusual interest, but even this well-beaten track suggests some good ideas as to rate of flow of the upper and lower strata of the aërial currents forming the trade-winds. Barbados was made in thirteen days, where, amongst other vegetable treasures, he obtained the fruits of the sandbox-tree (*Hura crepitans*), the explosive nature of which is well known, though not the violence of its character, which would suggest an alternative name of the dynamite-tree. Mr. Ball carried away a specimen packed in a wooden box, which he subsequently placed in his herbarium room in London, where, nine months after it had been obtained, it burst with such violence that the box was broken to pieces, and the valves and seeds of the fruit were scattered all about the room.

A single day at Jamaica afforded him his first glimpse of a thoroughly tropical vegetation *in situ*, and it would be difficult to find a terser or better description of its appearance to a Londoner than his simple statement that "it seemed to me as if the inmates of the Palm House at Kew had broken loose and run scrambling up the rocky hills."

The Isthmus of Panama crossed and the Pacific reached, the real interest of the voyage begins. The first impression Mr. Ball gains—suggested by the breadth of the Bay of Panama (120 sea[1] miles across)—is of the vastness of the geographical features of America as compared with the ideas formed of them from experience of "our diminutive European continent," and from maps, and especially from those on Mercator's projection. In respect of this last he not inaptly complains that it profits nothing to explain, even to the most intelligent youth, the nature and amount of the errors involved in that mode of representing a spherical surface on a plane; and he goes on to say: "I verily believe that all the mischief done by the stupidity, ignorance, and perversity of the writers of bad school-books, is trifling compared to the amount of false ideas spread through the world by the production of that respectable Fleming."

A few hours botanising in the coast forests of Buenaventura, a port on the coast of Columbia, yielded a harvest of plants which forged the first link in a chain of reasoning that has led Mr. Ball to the conclusion (opposed to the view of all other writers on the same subject) that the most marked division of the flora of tropical South America is not that between the regions east and west of the Andes; for on his arrival in Brazil he found that, though he was nearly 3000 miles from Buenaventura, and separated from it by the great barrier of the Andes, the plants of the forests of that country were almost all nearly allied to Brazilian forms. This is followed by a bold speculation, dwelt on at greater length towards the conclusion of the work, that "the ancestors of the Brazilian flora, and to a large extent also those of the Andean flora, came into existence in the ancient high mountain ranges of Brazil, where we now see, in the vast extent of arenaceous rocks, and in the surviving pinnacles of granite, the ruins of one of the greatest mountain regions of the earth."

Crossing the equator, our naturalist was disappointed in not seeing Chimborazo, still in popular estimation the "hub" of the South American continent, though geographers have long known that it has to bow its head to Aconcagua, upwards of 2500 miles further south. Chimborazo is only seventy miles from Guayaquil, whence it is easily seen on clear days, but we are told these occur only about half a dozen times in the year!

Cape Blanco, the westernmost cape of South America, rounded, the so-called rainless zone of South America, which extends for nearly 2000 miles to the southward, is reached. This is a feature of the highest interest to the biologist and meteorologist. Its access was signalled by the sudden fall of temperature from an average of 80°, with a relaxing atmosphere "heavily charged with vapour,"[2] to 74°, with an elasticity in the air that dispelled a previous lassitude, which had rendered burdensome even the first taste of the charms of tropical scenery.

In no part of the world is a change in vegetation more suddenly effected than in the short distance, amounting to little over 100 miles, between the Gulf of Guayaquil and

---

[1] Surely an oversight for English miles.

[2] When shall we have accurate conceptions embodied in our colloquial phraseology? The vapour of water is lighter than atmospheric air, yet the latter is conventionally described as "heavily laden" with it.

Payta. Nowhere in the world are the forests more luxuriant than in the former place, whereas, on arriving at Payta, Mr. Ball was informed by the officers of the ship that it was no use his taking his botanical box ashore with him, because the country was absolutely without vegetation. As, however, the forewarned expected, this was not quite the case: stunted bushes grew in the cliffs, nor were plants absent on the plateau above, where, however, the vegetation was more scarce than he had anywhere seen it, except in the tract west of the Nile above Cairo. He remarks that the gullies furrowing the seaward face of the plateau show that heavy rains must visit this part of the coast, and on inquiry he was informed that abundant rain, lasting for several days, recurs at intervals of three or four years. This, he subsequently found, is a normal feature of the rainless zone, added to which he was informed that slight showers occur at intervals a few times in the year, which suffice to maintain the vitality of the few species of plants that hold the ground persistently; whilst the heavier rains are followed by an outburst of herbaceous vegetation covering the surfaces that have long been bare.

For the existence of this rainless zone Mr. Ball considers that the hitherto assigned causes are insufficient. These are: the influence of the Andes in condensing the Atlantic vapours brought by the westward atmospheric flow; the warming in its passage north of the vapour-bearing aërial currents that accompany the Antarctic or Humboldt oceanic current; and the effect of this warming of the air in enabling it to hold in suspense all the vapour it absorbs in its passage north. Mr. Ball's principal objections to the sufficiency of these causes are that the Andes of Ecuador and Columbia do not condense the western vapour-bringing winds, whilst those of Peru, Bolivia, and North Chili do; and that the littoral zone of the former regions is, for a distance of 800 miles, even moister than parts of the coast of Brazil and Guiana. His supplemental explanation is based chiefly on the physical features of the Andes. In Peru the Andes present four parallel longitudinal chains, increasing in mean elevation in going westward, though the highest peaks are not on the westernmost range. In Ecuador only two such ranges, the two westernmost, exist, and these do not suffice to drain the vapour-bringing winds, a portion of whose moisture is precipitated on the Pacific coast. In Columbia, again, there are three of these parallel ranges, enough perhaps to drain the easterly winds; and its sources of moisture may be supposed to be derived from the diversion southwards of easterly currents from the Caribbean Sea which have crossed the Isthmus of Panama. On the whole, however, Mr. Ball considers that the influence of the Humboldt currents, oceanic and aërial, is of far greater moment than is that of the Andes, since the influence of these currents is felt even to the north of the Gulf of Guayaquil, as at Cape St. Elena, where the rains are less frequent than at Guayaquil. For the further description of this interesting subject we must refer to the work itself.

On April 15, Callao, the port of Lima, was reached, and a ten days' expedition to the higher Andes was effected. For this there were two railroad facilities. One line starts from the coast at Mollendo, south of Callao, and, running by Arequipa, crosses the crest of the Andes, and terminates at Lake Titicaca, 12,800 feet above the sea. The other starts from Lima itself. It was projected with the intention of piercing the crest of the Cordilleras at an elevation of 15,645 feet above the sea, thence descending to Oroya, a plateau between the main ranges. Its ultimate object was to afford a route to the fertile districts on the eastern slopes of the Andes. As yet it has only reached a village called Chicla, 12,200 feet above the sea, its progress having been stopped by the war between Peru and Chili. The first of these routes was obviously the most desirable for a naturalist, but want of time and the fact of Arequipa being in possession of a Peruvian force drove Mr. Ball to take the Chicla route. To the professed naturalist Mr. Ball's observations on this little expedition offer much of interest, but the season was unfavourable for botanising, the weather at the culminating point wretched, and the natural features of the country, under such conditions at any rate, anything but inviting. There is a brief discussion on mountain sickness, of which Mr. Ball has already detailed his symptoms in this journal (vol. xxvi. p. 477). They are anomalous; but as his elevation was only 12,200 feet, at which many mountaineers who suffer acutely at 16,000 feet and above it feel no inconvenience at all, his experience is insufficient. That the symptoms should disappear during bodily exercise is opposed to what is described in the cases not of man only, but of cattle, sheep, and horses, in crossing high passes. The observations on the temperature of the upper Andean regions as compared with that of the coast are very valuable, as are the notes on the zones of vegetation, the ranges of species, the distribution of endemic forms, &c.

On his return to Lima, Mr. Ball obtained some further information regarding the well-known hollowed cliffs of volcanic rock which occur along the coast, and reach to 700 feet above it, and which have been written of by Lyell and others as indications of a rise of the land. According to a very intelligent local observer, Mr. William Nation, of Lima, the excavations are due chiefly to a cryptogamic plant which grows on the surface of the cliffs, and is in active vegetation as a disintegrating agent during the dense fogs that prevail for many months of the year. Mr. Nation thinks that alternations of dry and damp air, by causing the cells of this burrowing plant to expand and contract, effect the removal of scales of mineral matter from the surface of the rock, and hence eventually excavate the latter. Fancying that the plants might (as do some lichens) chemically affect the rock, Mr. Ball submitted specimens to an eminent cryptogamist, who found it to be an Alga, and harmless in this respect. Mr. Ball himself is disposed to think that vicissitudes of temperature aided by alternations of moisture and dryness, dry fog and sun, may play the greatest part in effecting the hollows. It is to be hoped that Mr. Nation will follow up the problem, which wants only careful observation to solve it.

Between Callao and Coquimbo, along a monotonous coast, several places were visited, but these seem to be far from being oases; some of them, indeed, are dependent on transport by sea for a supply of fresh water. The track between Arica and Copiapo, a distance of 600 miles, "further than from Liverpool to Oporto," is that in which the rainless zone is most pronounced. With the possible exception of Pisagua, there is no inhabited place where drinkable water is to be had, and yet the wants (or greed) of men have established many industrial settlements along the coast for the purpose of working mines of silver, copper, and lead, and digging deposits of alkaline nitrates. Drinking-water is, in most of these towns, provided by the distillation of sea-water; in others it is imported. Nine such places were touched at by the steamer; their features were uniform, and, we may add, uniformly repulsive: chemical works with tall chimneys, sheds of reeds for workmen, a few clean-looking houses for managers, and grog-shops. At one of these, Tocopilla, Mr. Ball observes:—"At last I found, what I had often heard of, but in whose existence I had almost ceased to believe, a land absolutely without a trace of vegetable life. Not only was there no green thing; not even a speck of lichen that I could detect, though I looked at the rocks through a lens. Even more than by the absence of life I was impressed by the appearance of the surface, which showed no token that water had ever flowed over it. Every edge of rock was sharp, as if freshly broken, and on the steep slope no trace of a channel furrowed its face. The aspect is absolutely that of the scenery of the moon—of a world without water, and without an atmosphere." Curiously enough, small birds, which live on stable manure, were the only trace of indigenous animal life; what they were Mr. Ball could not approach them near enough to see. Seaweeds, however, though scarce, occurred in pools left by the tide, and relieved the barren coast from the curse of being without vegetation. At Caldera, the port of Copiapo, vegetation begins, and, though the environs are sandy, bushes and inclosed gardens are to be seen, and at Coquimbo green is, in the spring at any rate, a dominant colour. On May 9, Mr. Ball disembarked at Valparaiso, and made that town and Santiago his headquarters for twenty days. During this period he made numberless observations on the scenery, climate, vegetation, and geographical features, many of which though referring to matters that are familiar to every scientific reader, abound in thought and shrewdness, and are exceedingly instructive. Leaving Valparaiso, the voyager entered a totally different region of America, physically and biologically, and into it we shall follow him in a future number.

(*To be continued.*)

COLEOPTERA OF THE BRITISH ISLANDS

The Coleoptera of the British Islands. A Descriptive Account of the Families, Genera, and Species indigenous to Great Britain and Ireland; with Notes as to Localites, Habitats, &c. By the Rev. W. W. Fowler, M.A. Vol. I. Adephaga—Hydrophilidæ, Pp. xxii. and 269. Two Plates. (London: Lovell Reeve, 1887.)

DURING the last thirty years, seven or eight distinct catalogues of British Coleoptera have been published, and have met with an encouraging sale; hence there can be no doubt that there exists a considerable number of collectors of British Coleoptera. But no really satisfactory systematic work on this department of the faunæ of our islands exists, and Mr. Fowler has done well in attempting to supply such an one. The earlier works of Curtis and Stephens are, for obvious reasons, of little practical use in the present day, and though, twelve years ago, Mr. H. E. Cox published a hand-book of British Coleoptera in two volumes, it cannot be said to have been the work required, owing to the facts that it contained no reference to localities, and that it consisted entirely of systematic tables, without the addition of any matter that could make it a pleasant book to use.

In the work now before us, the author has been very successful as regards these points; he adopts the system of tables, but gives, in addition, brief diagnostic descriptions of all the species, and satisfactory details of localities and the distribution in our islands. In his prefatory remarks he very properly calls attention to the necessity of access to collections of an elementary nature, so that the student shall have some elementary notions about, at any rate, a few beetles before attempting to use the work. There can be no doubt that he is quite correct as to this point, and it may be hoped that the local museums and school collections that are now becoming numerous throughout the country will be of great use in this respect; and for this object such institutions should possess a small but well-selected general collection in addition to that of their local fauna.

There are now about 3200 species of Coleoptera on the British list, and the present volume deals with only about one-sixth of these, so that the work when completed will be of considerable extent. The author promises to give, when it is concluded, an introduction to the system of classification employed in it. This is, indeed, indispensable, as at present the student is not supplied with any definitions of the "series" which form the basis of the arrangement used. He already finds, however, under the various subdivisions, remarks on classification and affinities; these are usually well considered, and will, no doubt, increase greatly the interest of the work, and, it may be hoped, will induce the student to extend his studies to questions of greater interest and importance than the determination of the names of species.

The Coleoptera are an enormous order of insects, comprising already fully 100,000 species, and as their organisation is such that the details of their external structure can be readily observed, much has already been done towards establishing a natural classification of the order. The author has made himself well acquainted with the various recent improvements in this department, and acknowledges in the frankest manner his obligations to authorities in various parts of the world. There are some points of general interest as to the British Coleopterous fauna, such as the number of species peculiar to the islands, but the work before us has not yet sufficiently advanced to enable such points to be discussed with advantage, and we may perhaps find occasion at a future time to consider them.

It would be a very great advantage if zoologists could agree on a system of names for the various aggregates larger than genera. Mr. Fowler's work only gives the individual names of these larger aggregates, and distinguishes them merely by rather slight typographical distinctions; as a consequence, the student finds himself introduced to a large number of these names in rapid succession, and they must be rather a source of bewilderment to him than a key to the classification adopted; it would probably be an improvement if, in future volumes, the author would prefix to these names the terms "Family," "Sub-Family," "Group," &c., so as to allow the systematic value of the names themselves to be more readily appreciated. The two plates accompanying the volume are intended to give an idea of those structural characters on which the classification used in the work is based, and they also give three figures of larvæ borrowed from Schiodte; it may be hoped that these latter extraordinary forms may incite some student to continue the work of investigating the earlier stages of beetles, so ably pursued by the talented Dane whose recent decease is still a matter of general regret amongst entomologists. The structural diagrams II. and III. on Plate A are, as given, far from being successful. They are described as representing the under-skeleton, but, actually, one-half of each of the diagrams represents the upper surface, and the manner in which the two halves are connected will inevitably suggest to a beginner that the structures displayed are those that would be seen on removing the parts covering the upper surface.

Mr. Fowler, as we have already stated, has taken great pains to make himself acquainted with the modern authorities, and to render his work as interesting as the nature of the subject and its great extent will permit; his efforts in these directions will no doubt be duly appreciated, and his work will, it may be hoped, find a place in the libraries of all our local museums, as well as on the book-shelves of the amateur. D. S.

BRITISH STALK-EYED CRUSTACEA AND SPIDERS

British Stalk-eyed Crustacea and Spiders. By F. A. A. Skuse. (London: Swan Sonnenschein, Lowrey, and Co., 1886.)

THIS is a modest little volume of 126 pages, professedly written for the "tyro." We are informed, on p. 14, that the "pages do not profess to be either scientific or in the least anything beyond the production of a humble admirer of Nature, and only intended to put the reader on the road to the investigation of the creatures written about." This being so, it would be unfair to judge the work from the stand-point of more special treatises, and we need do no more than comment upon the introduction of a somewhat antiquated system of classification and of minor errors which would be unpardonable in a work of greater pretensions.

The book is a clearly stated compilation, and is, so far as it goes, fairly accurate and up to date. There is, manifestly, little room for originality, and the reader must be prepared to find that most of the more pleasing passages—those dealing with the habits of the animals described—are, of necessity, quotations from earlier authors, references to whose works are in all cases given as footnotes.

The subject-matter is apportioned into nine chapters and an introduction, and it deals with methods and accessories as fully as with the animals themselves. Under the head of Development (Chapter III.) are to be found the facts of morphology and physiology which fall within the scope of the work. It is in this that the author is at his worst, and there is much here which stands in need of revision. We are told, in the introduction, that "the earliest known insects have been found in the Devonian, so probably there also existed spiders." Taking the context into consideration, it is surprising that the author should thus presuppose the discovery of Palæozoic spiders, and overlook that of Silurian scorpions and cockroaches, the former so well to his purpose.

"Big-tails," "Queer-tails," and "Little-tails" are renderings of *Macrura*, *Anomoura*, and *Brachyura* as unfortunate as they are unconventional.

The illustrations are good as a whole; some are excellent, being faithful copies of standard figures. More spiders might be advantageously delineated, and exception must be taken to the wretchedly wooden drawings of crustacean larvæ, especially of the young lobsters (p. 27). For the latter the author would do well to substitute, should a second edition be demanded, the strikingly truthful drawings of Sars ("Om Hummerens postembryonale udvikling," Christiania, 1874), or, failing those, Kent's figures ("International Fisheries Exhibition Literature," vol. vi. "Conferences").

There is much truth in the author's assertion (p. 10) that "everybody knows a crab. Everybody knows a spider. But it is just these every-day things that people know really least about; while, on the contrary, things that must be sought for in order to be seen are often most commonly known." The writer is true to this tenet, and his book ought, in the hands of an intelligent "tyro," to be productive of good results; while passages such as that in which he describes (p. 73) the construction of the spider's web are well calculated to arouse that enthusiasm which he is sanguine enough to presuppose. The appreciation of the beautiful in Nature must precede the devotion to that which is more useful, and the little handbook before us, invested, as it is throughout, with a true dignity of purpose, will serve as a means to this desired end.

OUR BOOK SHELF

Catalogue of the Fossil Mammalia in the British Museum, (Natural History) Cromwell Road, S.W. Part IV. Containing the Order Ungulata, Sub-order Proboscidea. By Richard Lydekker, B.A., F.G.S. (London: Printed by Order of the Trustees, 1886.)

THE collection of Proboscidean remains preserved in the British Museum is by far the largest in any Museum in the world; containing as it does the splendid collections made in the Siwaliks of India by Sir Proby T. Cautley, the unrivalled British series of mammoth remains, the unique collection of pygmy-elephant remains from Malta, the series of remains of dinotherium and mastodon, from Eppelsheim, &c., and a fine collection of American mastodons from the United States and from South America.

An immense collection like this, containing remains belonging to nearly all the described forms, was admirably adapted for the study of transition forms, and Mr. Lydekker has not been content in this Catalogue with giving merely a detailed enumeration of the contents of the cases, but has written a full account of the families, genera, and most of the species of the known extinct Proboscidea. In a short introduction he gives some most interesting notes on the geographical and geological distribution of the species. In reference to the subject of the structure of the cheek-teeth Mr. Lydekker thinks that this can be traced from the most generalised to the most specialised member of the Elephantidæ. So complete indeed is this transition that not only is there no real line of demarcation between Mastodon and Elephas, but several of the species of the two genera seem to pass so imperceptibly into one another that it is not unfrequently a matter of extreme difficulty (if indeed it be not an absolute impossibility) to determine to which species individual teeth really belong.

In regard to geographical distribution, there appears to be considerable evidence in favour of an easterly migration of the mastodons having taken place from Europe to India; while the restriction of the stegodont group of elephants to the latter country and the regions to the eastward, points to the conclusion that the transition from the mastodons to the higher elephants took place in those regions. From this we may also infer that there subsequently ensued a westerly migration of these higher forms to Europe, and finally on to North America, where the true elephants did not make their appearance till the Pleistocene, and then appear to have been represented only by two species, one of which ranged over the greater part of the higher latitudes of the northern hemisphere. The descriptive details are very usefully illustrated by a number of woodcuts of the teeth and cranial bones. The work, despite its name of Catalogue, is a most important contribution to our knowledge of the subject.

LETTERS TO THE EDITOR

Iridescent Clouds

THIS phenomenon is very common here in the winter, occurring, with few exceptions, whenever there are scattered clouds near the sun. The colours are often brilliant enough to catch the attention of the most casual observer, but at other times they can only be made out with the aid of dark neutral-tint spectacles. These reduce the intensity of the glare near the sun to a point favourable to the discrimination of colour.

I have lately been watching the somewhat complicated phenomena, and taking rough measures of the angular distances of the various colours from the sun, and I have little doubt that the colours are due to diffraction of light by fine particles of ice.

Within a circle, radius about 2°, the clouds are white, perhaps faintly tinged with blue; but it is difficult to observe a delicate shade of colour so near the sun. This circular space is surrounded by a ring of yellow or orange. The region of most vivid hues is comprised between 3° and 7°, the most striking being purple, blue, orange, green, and red. These are not arranged in rings, but are distributed over the thinner parts of a cloud in irregular patches. Beyond this region the only colours visible are green and red, becoming fainter as the distance from the sun is increased. I have detected them in three or four cases at a distance of 21°. At some distance from the sun the greens and reds are frequently arranged in bands parallel to the edge of the cloud, sometimes as many as three bands of each being visible. I have often seen a cloud completely encircled by bands, the impression given to the observer being that the colour depends on the thickness of the cloud. No doubt the real explanation is that the ice particles are larger in the interior of a cloud. We have thus two independent factors to determine the colour of a particular portion of cloud: the distance from the sun, and the average size of the particles. Near the sun slight variations of the former are more important, so we get a tolerably regular yellow ring. Far from the sun the variations of the latter have overwhelming influence, and we have bands along the edge of a cloud. At a medium distance, in the region of vivid colour, we have the two factors nearly equally powerful, and indescribable confusion as the general result.

On one occasion, when the edge of a large cloud passed almost through the sun, I noted down the colours in order along the edge, where the size of the particles would be tolerably uniform: white, yellow, red; blue, green, yellow, pink; green, faint red. This list consists evidently of three successive diffraction spectra, and it is in satisfactory agreement with a number of less complete series that I have obtained. The blue, however, is often replaced by a brilliant purple, due to the first and second spectra overlapping. Another method of discovering the true order of the colours is by watching the changing hues of a cloud approaching or leaving the sun. This tended to corroborate the list just given, but I could seldom trace more than two or three changes, so rapidly did the clouds grow or dwindle away. I noticed, indeed, that the more rapid the growth the more brilliant were the colours displayed. One interesting observation deserves special mention. A cloud showed faint colour at a great distance from the sun. It was edged with green, with red inside. As it approached the sun, the bands moved inwards, and red appeared on the edge, then green, then red, then green. The last tint was very undecided, and afterwards the whole cloud remained white. The inward motion of the bands showed that the inner particles were larger.

We now come to the question of the form of the diffracting particles. The form most favourable to diffraction is the sphere, as with a sphere the angle of diffraction for any given spectrum depends only on its diameter. Thus if a cloud be composed of spheres of uniform size, and be at the angular distance from the sun corresponding to the first spectrum for that size, each sphere will send its quota of light to the observer. Next to the sphere comes the circular cylinder. In order that a cylinder may send diffracted light to the observer, its axis must lie in or near the reflecting plane. By the reflecting plane I mean the plane of a mirror which would reflect sunlight to the observer. But, when this condition is satisfied, the angle of diffraction, corresponding to any particular spectrum, depends only on the diameter of the cylinder. Any other form, a circular disk for instance, gives different diffracting angles according to the orientation of the particle. The spectra corresponding to different orientations would be superimposed and white light be the result.

Now, among the manifold forms of snow-crystals there is, I believe, nothing approximating to a sphere. But thin hexagonal prisms are common, either separate, or attached as rays to hexagonal disks. These would produce much the same effect as circular cylinders; for the extreme variation of the apparent diameter of an hexagonal prism from its mean value is only 7 per cent.

Granted that the diffracting particles are hexagonal filaments, my measurements of the angular distances of the colours from the sun supply data for determining the average diameter of the filaments. For this purpose purple is a useful colour, as it always arises from the overlapping of the first two spectra. I took some five-and-twenty measures at various times, which varied from 3¼° to 6¾°. These give diameters from ·017 mm. to ·009 mm. Orange of the first spectrum ranged from 2¼° to 5½°, six measures. These give diameters from ·021 mm. to ·010 mm. Blues of the second spectrum, four measures, 4½° to 6¾°; diameters ·014 mm. to ·009 mm. If the colours I observed at 21° from the sun were produced by filaments ·013 mm. in diameter, they must have belonged to the ninth spectrum. But the ninth spectrum, in addition to being only one-fortieth as bright as the first, is overlapped by four spectra of higher order and three of lower, so it can hardly be distinguishable. At such a distance from the sun the finer particles would have a great advantage in colour-producing power, so I think it probable the spectrum was of the fifth order, produced by particles of diameter ·009 mm.

The next difficulty is to explain why colours are not seen in clouds composed of minute spheres of water. As explained before, the spherical form has a great advantage. I find by calculation that if the spheres were of uniform size, diameter ·013 mm., the colours of the first spectrum would be about twenty times as brilliant as if the cloud were composed of filaments of the same diameter, arranged at random, but occupying the same fraction of the field of view. So we might *a priori* expect that water clouds would be more brightly iridescent than ice clouds. But it is not so. During the summer here I looked frequently and vainly for iridescence. This want of colour must arise from the minute drops not attaining sufficient uniformity of size. So we have to find some cause of uniformity which acts more powerfully on particles of ice than on drops of water. I venture to offer the following suggestions.

Let us consider what happens when an ice cloud is forming. Dust particles, no doubt, act as nuclei to ice crystals as well as to water drops; so that a number of crystals will start into existence about the same time. Soon there will be no more dust particles of sufficient size to form nuclei. The rate of deposition on a crystal will be proportional to its surface, so all the crystals will grow in diameter at the same rate. The ratio of the largest diameter to the smallest will become less. In fact the crystals will become more uniform in size. No doubt, too, the supply of aqueous vapour near a large crystal will be consumed more rapidly than it can be refunded by diffusion. So the larger crystals will grow somewhat more slowly. These are causes tending towards uniformity. They account for the observed fact that they are newly formed clouds, which show the brightest colours, though when they first come into view they are white. It is easy to give reasons why some clouds should lose their colour so soon. Varying conditions may affect the growth of different layers of particles in a different manner, or a slight increase in the rate of deposition may call new dust particles into action.

In the case of water clouds there are two special causes brought into action against uniformity. Sir William Thomson has shown that the maximum vapour-tension at the surface of water is largely increased when the surface is highly convex. So the large drops will grow more rapidly than the small ones, and the range of size will be more and more extended. Secondly, whenever two drops of water come into collision, they will combine into one larger one.

In conclusion I may remark that St. Moritz is 6000 feet above sea-level, and the iridescent clouds were generally above the surrounding mountains, *i.e.* at least 11,500 feet above sea-level. On some days the sky was overspread at a great height, with a thin haze gathered here and there into denser streaks (cirro-stratus?). The haze sometimes formed coronæ close around the sun. I have not made out more than two spectra. From rough measures of the diameters of the rings, I find for the diameters of these filaments values varying from ·04 mm. to ·07 mm.

St. Moritz, Switzerland, March 14

Aino Hairiness and the Urvolk of Japan

IN Mr. B. H. Chamberlain's remarkable and instructive monograph on the Ainos, contained in the first number of the Memoirs of the Literature College of the Imperial University of Japan, just published, will be found an explanation of the different conclusions that have been arrived at by different observers as to the *hairiness* of that singular people, equally isolated, so far as our present knowledge extends, by language and by physical characteristics from all surrounding races. When I spent some days among these so-called savages in 1865 or 1866, I had the opportunity of examining some four or five score of them, chiefly men, and in every individual I found the phenomenon of hairiness more or less marked. The sternal, inter-scapular, and gluteal regions were, in particular, thus provided with a natural covering, the very regions where such a protection from the drip of rain would be most serviceable. I remember well that in some individuals the gluteal fur was so abundantly developed that thick tufts of hair, several inches long, could be grasped in the hand. But recent travellers have been struck by the number of natives they met with deficient in hairiness—whether they were proportionately lacking in face-hair is not stated—and it has been doubted whether hairiness is really an Aino characteristic. Dr. Baelz's investigations have, however, amply vindicated the claim of the Ainos to be the hairiest people in the world, and now Mr. Chamberlain shows that the smooth-bodied natives are in fact half-breeds, the progeny of native mothers by Japanese fathers. Unions of this kind have probably increased in frequency during the last two decades. Between the two races, however, some incompatibility seems to exist, for their progeny exhibit a diminished fertility. "The second generation," says Mr. Chamberlain, on the authority of the Rev. Mr. Batchelor, who has lived for years among the Ainos, and contributes an exhaustive grammar of their language to the volume of Memoirs before me, "is almost barren; and such children as are born—whether it be from two half-breed parents, or from one half-breed parent and a member of either pure race—are generally weakly. In the third or fourth generation the family dies out."

The injury to the reproductive system caused by this "miscegenation"—a phenomenon not unparalleled in the history of man, and proving the existence in man, as in other organisms, of a tendency to specific variation—has an important bearing upon the much-debated question of the proportion of Aino blood that runs in the veins of the Japanese of to-day. Mr. Chamberlain, chiefly from philological considerations based upon an examination of place-names, arrives at the conclusion that the *Urvolk* of the Japanese group, from the extreme south to the furthest north, was an Aino race, and we know from history that up to the time of Yoritomo (twelfth century A.D.), and probably later, the northern half of the main island was still, to some extent, peopled by Ainos. Yet even the northern Japanese are smooth-bodied, although it is extremely unlikely that "miscegenation" did not obtain between their Japanese ancestors and the aborigines. In the light of Mr. Batchelor's observations the explanation of this apparent anomaly is easy. The half-breeds died out, and the prepotency of the Japanese in numbers and civilisation gradually expelled the Aino element from the population, which has thus become an almost purely Japanese one.

It must not, nevertheless, be forgotten that at least two distinct races may still be traced in the existing population of the Japanese group. One is slim, high-headed, and often aquiline-nosed; the other stouter and broader, more brachycephalic, and flat-nosed. Excellent types of both, especially of the first, will be found in Siebold's "Nippon Archiepf." The former constituted the military class of Old Japan, the latter the peasantry; and of the latter some degree of hairiness of the limbs is a not uncommon characteristic. The drawings of Hokusai sufficiently prove this assertion, which the experience of every resident in Japan will confirm. It may therefore be safely assumed that the elimination of the Aino element has not been complete. For my own part I believe that the earliest inhabitants of Japan were tribes of Malayo-Polynesian blood coming from the south, and of Aino blood coming from the north. Altaic immigrants followed, and, partly perhaps through some degree of reproductive prepotency, gave a characteristic and predominant stamp to the population without total elimination of its aboriginal elements.

Units of Weight, Mass, and Force

HAVING read with much interest Prof. Greenhill's letter in NATURE of March 24, p. 486, I am inclined to think that much of the perplexity felt by some who begin the study of dynamics arises from the want of names for the units of the various magnitudes with which the science deals. We have names for units of time, space, mass, force, work; but no names for units of velocity, acceleration, impulse, momentum, &c. I venture to suggest the following:—Let the unit velocity be that with which a point describes uniformly one foot per second. Let this unit be called a vel. Let the unit acceleration be that whereby the velocity is uniformly changed by one vel per second. Let this unit be called a cel. Then everything becomes clear. *E.g.* the meaning of the equation $W = mg$ is seen to be this: The weight of a mass of m pounds at a place where the acceleration arising from the mutual stress between it and the mass of the earth is g cels being W poundals, the *numbers* W m g are connected by the equation $W = mg$. Then, for the sake of the beginner, let the names of the units be given thus: $W = mg$ poundals, $m = \frac{W}{g}$ pounds, $g = \frac{W}{m}$ cels. It is too common to see acceleration expressed in feet per second, instead of in vels per second. If the weight of a mass of m pounds be defined to be the mutual stress between it and the mass e pounds of the earth, it is evident that the weight of e attracted by m is the same as the weight of m attracted by e; and, in the absence of either, the other would have no weight.

Bardsea, March 29 EDWARD GEOGHEGAN

The Earthquake in the Riviera

THOUGH there can be no question as to the amount of damage done by the late earthquake—I am writing in a shed, the hotel being destroyed—I think that the violence of the shock has perhaps been very greatly exaggerated. I have only been able to make a flying visit to this place and to Diano Marina, but I cannot help being struck by the fact that the peculiar architecture is the main cause of the large amount of destruction.

Indeed, judging from the small amount of damage done to buildings in which flat or square stones and flat floors have been used, I should doubt whether the shock was much more severe than that which not long ago damaged the brick buildings in East Anglia.

At both Oneglia and Diano Marina the building material is usually rounded stones from the beach, or rubble with stones of all shapes and sizes. The stucco is apparently expected to make good any deficiencies. Besides this the floors are nearly always brick arches abutting against the vertical walls, without any reference to other lateral support. Most of these houses are three or four stories high. Of course any vibration affecting buildings of this construction will split the walls in all directions, for besides the lateral thrust of the arches, the walls are full of wedge-shaped stones ready to slip into any fissures which may form.

The complication caused by these arched floors makes it very difficult to trace the direction or angle of emergence of the shock.

CLEMENT REID

Oneglia, March 13

Scorpion Virus

ALLOW me to state that the results of my experiments on Cape scorpions are in full accord with Prof. Bourne's conclusion that the poison of the scorpion has no fatal effect on the same individual or another individual of the same or even of another species. Speaking before the South African Philosophical Society in February 1883, I said :—"Members of the Society will see on the table a scorpion of the larger (Cape) species. That scorpion I caught at 11 o'clock this morning. I at once pierced him in three places with his own sting, on which in each case there was a drop of poison. In the last inoculation I held the sting in the wound, and squeezing the 'bulb of the sting' with the pincers forcibly injected poison. The creature is alive and active" (Proceedings for 1883). These and subsequent experiments, however, led me to believe that the poison has *some* effect, causing sluggishness and torpor for a while. I quite agree with Prof. Bourne that it is physically possible for a scorpion to sting itself in a vulnerable place; and though I never was able to observe the infliction of a wound on itself by any scorpion, I can well believe that this is possible, but, I am convinced, wholly accidental.

I found also that the poison of the ring-hals snake (*Naja haemachates*) was not fatal when inoculated in the same individual or another individual of the same species.

The Supposed Myzostoma-cysts in *Antedon rosacea*

SOME eighteen months ago I called attention in these columns (vol. xxxii. p. 391, and vol. xxxiii. p. 8) to certain malformations which I had discovered on the pinnules of *Antedon rosacea* from various British localities. They often take the form of small cysts which are very like those produced by encysting Myzostomida on the arms and pinnules of various Crinoids from the Pacific; and as no other cyst-builders but *Myzostoma* were then known to infest the Crinoids, the inference seemed a natural one that the cysts on the pinnules of *Antedon rosacea* had been produced by a small member of this genus. I subsequently found several more cysts on some examples of *Antedon rosacea* which were dredged at Gibraltar by the Italian corvette *Vettor Pisani*, and the whole collection was sent to my friend Prof. L. von Graff for examination.

To our great surprise, however, he has not found a single *Myzostoma* in any one of the fourteen malformations of the pinnules, whether cysts or otherwise, which he has opened; and "the new British Myzostoma" must therefore be disestablished.

But what, then, has been the cause of these malformations? Prof. von Graff has found them to be always associated with the presence of a minute globular body, which has the appearance of an egg that has undergone superficial cleavage, but yet exhibits no trace of nuclei when stained. It is impossible to decide at present what this structure may be. Prof. von Graff has described it more fully in a "Supplementary Report on the Myzostomida of the *Challenger* Expedition" which he has just completed. But its nature seems to be as problematical as that of the sacculi; and fresh material, not spirit specimens, must be examined before we can expect to learn much more about it. In any case, however, it would seem that we have to deal with a hitherto unknown parasite of the Crinoids, which is capable of producing modifications in the calcareous tissues of the arms and pinnules, of essentially the same character as those caused by *Myzostoma*, though of smaller size.

I would commend the question to the attention of those naturalists who may meet with *Antedon rosacea* in the dredgings of the ensuing season; and in order that they may know how to catch their hare, I shall be most happy to forward specimens of the cysts to anyone who desires to become acquainted with their external appearance. I may add that the largest cysts I have seen are on Comatulæ from the Cumbrae, Milford Haven, and Gibraltar; while I have no knowledge of their occurrence either at Naples or anywhere else in the Mediterranean.

Eton College P. HERBERT CARPENTER

On some Observations on Palæobotany in Goebel's "Outlines of Classification and Special Morphology of Plants"

THE few modern authors of botanical text-books who have ventured to summarise recent palæobotanical researches have achieved but moderate success. These authors have too little knowledge of the rapid progress of the study of fossil plants during the last few years to make success possible; hence, their summaries, if not absolutely inaccurate, are usually misleading. So long as these errors are confined to works published in Continental languages, British palæobotanists need not take the trouble to correct them. But the case is altered when English translations of these books appear amongst us. Palæobotany has nowhere made greater progress during the last few years than with ourselves. Many errors have been corrected, and new truths, results of careful and prolonged investigations, have taken their place. With the more important of these new discoveries many of our younger students of geology are now familiar. It is desirable that what they have been taught should not be contradicted by the utterances of authors ignorant of the subjects upon which they venture to express an opinion.

Some little time ago Dr. Goebel, of Rostock, published a volume which was virtually a new edition of Book II. of Sachs's "Lehrbuch der Botanik," and an English translation of this volume, made by Mr. H. E. F. Garnsey, and revised by Prof. I. B. Balfour, has just appeared. Dr. Goebel's volume contains some references to the Palæozoic flora which are seriously behind the times. To allow these statements to reach our students uncorrected will do harm, because they must suggest to those students that certain questions are still open and debatable which cannot now be regarded as such.

Had I not unfortunately misunderstood a wish expressed by my friend Prof. Balfour, some explanatory footnotes would have been introduced into the above volume, which would have rendered this communication unnecessary.

On p. 193 of the translation we find the following statement:—"Other groups are the Sphenophylleæ, Lepidodendreæ, and Sigillarieæ, the first of which are only heterosporous Lycopodiaceæ." We have no reasons for concluding that Sphenophyllum is Lycopodiaceous, still less that it is heterosporous. This latter statement rests upon M. Renault's interpretation of a minute *multicellular* fragment which he observed in a sporangium, and which he believed to be a macrospore; it could not be this, since the exosporium of a macrospore is a *unicellular* organism. On the other hand, the Lepidodendra were both homosporous and heterosporous. As to the Sigillariæ, even M. Renault now admits that all the vertically-fluted forms are Lycopodiaceous. The assertion that the Lepidodendra were all heterosporous is repeated on p. 196. On p. 272 we have a brief paragraph of eight lines remarkable for the number of the inaccurate statements which it contains. I have indicated these inaccuracies by reproducing them in italics.

"The Calamites are Equisetaceæ which appear in the older geological formations, *beginning in the Carboniferous Limestone* (1), culminating in the Coal-measures, and disappearing in the Permian formation. The spikes of sporangia are either not known, or so badly preserved (*Calamostachys*) (2), *that their structure cannot be determined; it remains doubtful, therefore, whether they were homosporous or heterosporous forms* (3). The stems *had neither leaves* nor leaf-sheaths, *or else these were transitory formations and soon fell off* (4). In other respects *the structure of the stems resembles that of the Equisetaceæ* (5).

Their surface was marked with ridges (6), and they had a central hollow divided by diaphragms."

I will examine these statements *seriatim*.

(1) The author appears to have been strangely ignorant of Sir William Dawson's magnificent discoveries of Calamites and other Carboniferous plants in the Devonian strata of North America, announced in his Report on the subject in 1871.

(2) In 1874 I published in the Philosophical Transactions the detailed structure of extremely beautiful examples of *Calamostachys Binneyana*, and, since then, Prof. Weiss, of Berlin, has figured equally fine examples of *Calamostachys Ludwigi*. In the Philosophical Transactions for 1881 I further showed that this genus comprehended both homosporous and heterosporous forms. At the same time Calamostachys is not the fruit of Calamites.

(4) Both Sir William Dawson and Prof. Weiss have shown that the slender twigs of Calamites were abundantly supplied with verticils of linear leaves.

(5) This statement is true with an important limitation, which Dr. Goebel ignores; or, as a follower of M. Renault, he more probably rejects. Whilst the type of Calamitean organisation is unquestionably Equisetiform, their arborescent stems and branches contained an enormous xylem or woody cylinder, developed exogenously, which made them differ very widely from their degenerate living representatives.

(6) This is a repetition of the old fallacy, which regarded the vertical groovings of the surfaces of the inorganic casts of the fistular medullary cavity as belonging to the cortical surface. We have now numerous sections of the Calamitean cortex, no one of which exhibits the slightest trace of vertical flutings; they are all smooth.

On p. 281, speaking of heterosporous Lycopodiaceæ, the author accepts M. Renault's old conclusions that in Lepidodendron "there is no certain indication of secondary growth in thickness." "The connection of fossil stems capable of great increase in thickness, such as the Sigillarieæ and Calamodendron is at present questioned." These facts are no longer capable of being justly questioned. The structure of *Lepidodendron Selaginoides* alone suffices to settle the matter so far as that genus is concerned; to say nothing of the many other species that demonstrate the same fact. M. Grand'Eury himself, long one of the most influential questioners, has now recognised that the genus Arthropitus only represents the thick woody zone of a true Calamite. Prof. Stur, of Vienna, long ago demonstrated in an unanswerable manner the almost absolute identity of Calamites and Calamodendron; and M. Renault himself, as I have already observed, has still more recently been compelled by the discovery of a Sigillarian fructification by M. Zeiller to alter his view respecting the Sigillariæ. He no longer insists that these cannot be Cryptogams because their stems grow exogenously, but now hands over to his opponents, who have so long contended for the Lycopodiaceous affinities of this Sigillarian genus, all the vertically fluted examples of it.

Whilst deeming it desirable that his readers should be put in possession of the other side of the question to which he refers, it is only fair to Dr. Goebel to say he is himself aware that those questions are dealt with in a one-sided manner. In a footnote on p. 272 of the English translation the author says:—"The short description given in the text from Renault may serve at least to draw attention to these interesting types, in which there is much that is yet uncertain. We cannot enter here into disputed or doubtful points." At the same time it is to be lamented that the leading botanists of the world cannot give us palæontologists more of that valuable aid which their special studies would so well enable them to do. I do not yet despair of enlisting some of the Strasburgers, de Barys, Goebels, and Van Tieghems in this honourable service. W. C. WILLIAMSON

Owens College

A Sparrow chasing Two Pigeons

ON Sunday, I asked three men what they were observing, when they pointed out a sparrow chasing two pigeons.

The pigeons were evidently greatly alarmed at their pugnacious attendant, who took occasional pecks at them when flying underneath, and whenever possible. The sparrow lost ground when the others made their more rapid doubling, but soon came up with them again, and renewed its attack.

What was the original quarrel of course we do not know, but the persistency of the sparrow's attack greatly amused us. Have any of your readers observed anything like this? or is there any record of the like? E. A. C.

Luton, Chatham, March 14

Top-shaped Hailstones

I DREW attention to hailstones possessing the above form in *Science Gossip* of December 1884. These pellets, which fell in my garden at Polmont, Stirlingshire, on the morning of May 6, 1884, were about one-fourth of an inch in length, and nearly three-sixteenths of an inch across. I did not see any horizontal stratification as observed by your correspondent Mr. Middlemiss, but found that each transverse section, when examined by a good lens, exhibited a fairly well-marked internal radiated fibrous structure, somewhat similar to that shown in sections of the mineral wavellite. Below are two (transverse and longitudinal) diagrammatic sections of the Polmont hailstones.

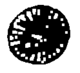

FIG. 1.—Transverse section (near base of cone) × 2.

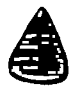

FIG. 2.—Longitudinal section × 1½.

Since then, however, I have found top-shaped hailstones composed of fibres radiating from the summit of the pyramid as shown in Fig. 3. ALEXANDER JOHNSTONE

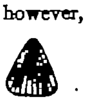

FIG. 3.—Longitudinal section.

FIG. 4.—Transverse section of Fig. 3.

Edinburgh University

A Peculiar Radiation of Light

AT 10.30 p.m. this evening, my attention was called to a peculiar radiation of light in the eastern sky. The centre of radiation was due east, and the bars on the *right-hand side* were increased in brilliancy by light evidently arising from the moon, which was not visible, but concealed by cloud. The extent of these rays was from horizon to zenith; the rays being of unequal size, but of a pale gray colour, slightly iridescent.

The east wind was blowing smartly at the time, and I should like to be informed whether this strangely beautiful appearance in the sky was caused by the radiation of light from a rising moon on thin clouds, or was it the effect of a strong current of wind from a given point?

By 11 p.m. the moonlight was full; the moon still to the right of the axis of the rays, and the rays nearly dispersed.

Falmouth, March 12 ROBERT D. GIBNEY

THE CHEMICAL SOCIETY'S ANNIVERSARY MEETING

THE anniversary meeting of the Chemical Society was held on Wednesday, March 30. We give some extracts from the address of the President, Dr. Hugo Müller, on the recent progress of chemical science:—

As we contemplate this ceaseless activity in chemical research now manifested all over the world, and which from year to year is continually on the increase, we are nevertheless bound to recognise the fact that vast as the work thus accumulated may appear, there remains still much to be accomplished. The more the field is worked the richer will be the harvest.

Overwhelmed by the quantity of material, especially in the direction of the production of new compounds, hasty critics were wont to denounce such work as superfluous, but it is now generally recognised that we must still continue with the patient and careful elaboration of the substructure of facts before we can with advantage proceed with the longed-for rearing of the edifice of a comprehensive scientific generalisation, that is to say, of ideal chemistry.

The infinite complexity which inquiry reveals in every direction bids us more than ever to be cautious in taking flight on the wings of speculation.

In the meantime we must content ourselves with the use of working hypotheses in the various fields of inquiry; these we develop and modify as we go on, or, it may be, discard in favour of others which for the time being seem more in accordance with the facts before us.

The triumphs of modern chemistry bear testimony that faulty and incomplete as our present theories undoubtedly are, our science is ever advancing.

It is now well understood that the most important data for the future extension of chemical theory will be derived from the interpretation of the results of investigations into the physical side of chemical phenomena.

The examination of the optical properties of chemical elements and compounds, the determination of thermo-chemical constants, and the verification of physical constants generally, are now pursued by a great number of investigators. Of late also the experimental inquiry into the connexion between electrical and chemical force is becoming a fruitful field of research; and we may hope that further determinations of the coefficients of conductivity of electrolytes will before long lead to a clearer perception of the intimate nature of chemical change.

To pass in review the chemical work published during the year, as some of my predecessors have done on similar occasions, has now become an impossible task, even supposing that the time at my disposal permitted me to do so. I am, however, tempted to refer briefly to a few results which strike me as particularly noteworthy.

The work accomplished in thermo-chemistry is, as I have already observed, very considerable, and thanks to the patient labour of many workers the results thus achieved are comprehensive enough to admit of a consideration of their general bearings. In this respect I wish to direct attention to the publication of Julius Thomsen's fourth and concluding volume of "Thermochemische Untersuchungen." This remarkable work is entitled to the highest appreciation of all who realise the manifold difficulties which beset the execution of thermo-chemical investigation. But while referring to the many highly important and remarkable deductions which the author draws from his experiments, we cannot at the same time help being struck by the many anomalous results and startling conclusions which he arrives at. It would seem that further determinations of the fundamental values, if possible by different and varied experimental methods, must be obtained before the full importance of this work can be entirely realised.

An important addition to our still very limited knowledge of the density of metallic elements in the gaseous state has been made by V. Meyer and Mensching, who have now succeeded in overcoming the great experimental difficulties formerly encountered in the determination of the vapour-density of zinc. The molecule of zinc has been found to be monatomic, like that of cadmium and of mercury, the only two other metals the vapour-densities of which are thus far known.

The remarkable results recently published by Crookes in his papers on the spectra of the so-called rare earths are still fresh in our memory, and the ingenious application he has made of the doctrine of evolution in this speculation on the genesis of the elements has not failed to attract the attention it deserves.

The further investigations of the chemical and physical properties of the new element germanium by Winkler, Nilson, and Petterson have established its chemical position, and the supposition that its proper place in the periodic system is that of ekasilicon has been confirmed.

Ladenburg's long-continued researches on conine have been crowned by success. He has effected its synthesis and has shown that it is identical with α-propylpiperidine. This must indeed be considered one of the most noteworthy achievements in organic chemistry of the past year, inasmuch as it is the first instance of the artificial formation of an optically active natural alkaloid.

Wallach found that the diazo-amido-compounds formed from diazo-salts and piperidine are for the most part well-characterised substances, and that when heated with concentrated hydrofluoric acid they yield the fluor-derivative in almost theoretical proportions. He has prepared in this way fluorbenzene, parafluortoluene, parafluornitrobenzene, parafluoraniline, and fluorphenyl, &c.

Studying the action of sodium on mixtures of ethers such as oxalic and acetic ethers, W. Wislicenus has discovered a new and ready method of effecting the synthesis of compound acids, and this reaction cannot fail to become of great value.

Brieger has succeeded in isolating a well-characterised alkaloid from the liquid used for cultivating a certain Bacillus which causes tetanus traumaticus in animals. This substance, which the author calls tetanine, seems to be the immediate cause of the toxic action of this Bacillus, and thus for the first time a specific pathological effect of a microbe has been traced to a well-defined chemical compound produced or secreted in its life-process.

Finally, I must also allude to the very remarkable observation recently published by Liebreich which demonstrates the fact that under certain conditions chemical reaction is retarded, and even altogether suspended. He noticed that in a mixture of aqueous solutions of chloral hydrate and sodium carbonate the formation of chloroform does not take place uniformly throughout the liquid. For instance, on performing the experiment in a test-tube there appears immediately below the meniscus a sharply defined space of 1-3 mm. thickness in which no reaction takes place. Similar results were obtained when an aqueous solution of iodic acid was mixed with sulphurous acid and soluble starch. The inert space manifests itself on the surface of the liquid which is in contact with the air or separated from it by a thin membrane. In narrow tubes the reaction is much more retarded, and it is altogether suspended in capillary tubes.

In my opinion this preliminary communication contains the germs of a discovery in a new direction, and the further study of the nature of these subtle influences which bring about the phenomenon in question must lead to important results.

In bringing this report to a conclusion I must briefly allude to a subject only indirectly connected with our Society, viz. the progress made in the organisation of technical education in this country, which, more particularly under the guidance and fostering care of the City and Guilds of London Institute, is gradually making its way.

Most of you are aware that the President of this Society is one of the *ex officio* members of the governing and organising body of this Institute, and it may be mentioned in passing that the regular attendance at the frequent meetings of the various Committees and Sub-Committees involves the necessity of devoting a by no means inconsiderable amount of time to this honorary office.

The chief event to be recorded in this connexion is the inauguration of the Central Institution which is to fulfil the function of a Technical University or Polytechnicum, and to afford higher scientific education to the future owners, directors, managers, engineers of manufacturing works, and the teachers in the various branches of technology. This magnificent Institution has now started on its career, and we have every reason to think that before long its value will be fully recognised by those who ought to take advantage of its existence. It is, however, unfortunate that the organisation of this Institution has stopped short of the plans originally laid down, and has been not at once carried to completion. Strange as it may appear, this is due to the want of funds. The City and Guilds in taking so prominently charge of the initiation and diffusion of technical education in this country, have thus far most liberally furnished the means required, and have thus earned the gratitude of the country; but as, the development of the scheme progresses an even and commensurate flow of further contributions is required, which, being voted in many cases but annually, at once demonstrates the somewhat precarious conditions on which this important enterprise is dependent.

It is to be hoped that a more general recognition of the absolute need of an education of a higher scientific character both for masters and men will before long have its proper effect; and that the ways and means will be forthcoming to carry out a work which promises so well, and that the Central Institution may then stand a fair comparison with numerous institutions of a similar kind in other countries which have already helped in so marked a degree to advance the industries of those countries.

The mistaken notion is still too prevalent that technical education has to confine itself to the theoretical considerations of known technical processes, and that a more extended acquisition of scientific knowledge is not required. It is obvious that a pupil educated on these lines may find by the time he is able to enter on his practical career that the processes with which he has been made acquainted have in the meanwhile become obsolete, and unless his education has been sufficiently comprehensive to enable him to strike out new lines for himself he will be ill fitted to compete with those who have been educated on a wider basis.

Essential as it is to impart to the future manager scientific knowledge, it is above all necessary to train him by practical work and research in the laboratory how to investigate a subject which may present itself in his daily occupation, whether it be some unexpected development in a new direction, or whether it be some new difficulty which confronts him in carrying out the processes under his direction.

It is self-evident that such knowledge and such practical experience in carrying out investigations is not to be attained by merely attending one or two courses in the lecture-room or in the laboratory. Those who mean to effectually qualify themselves for such functions can only accomplish this object by devoting years of patient and intelligent work under the guidance of the professor in properly appointed laboratories.

THE INSTITUTION OF NAVAL ARCHITECTS

THE spring meetings of the Institution of Naval Architects this year were, to a considerable extent, adversely affected by the recent death of Mr. William Denny, of Dumbarton, the eminent shipbuilder, who was for many years one of the most active members of the Council, and who was foremost amongst the mercantile shipbuilders of this country in the application of scientific methods to naval architecture. Mr. Denny, as is well known, set up at Dumbarton a large experimental tank similar to that contrived by the Admiralty at Torquay for the late Mr. W. Froude, F.R.S., and in which most of his famous experiments on the resistances of the hulls of ships were carried out. It is not often that manufacturers can be induced to spare time and money for the purposes of scientific investigation, even when such investigation is directly conducive to the success of their business. But Mr. Denny was an exceptional man. He firmly believed in the mercantile value of exact scientific knowledge, and he possessed the courage and the ability to act up to his beliefs. It is satisfactory to know that he considered himself fully repaid for the risks he ran in the results which he attained.

The opening address of the President dealt, as might have been expected in this Jubilee-year, with the remarkable progress in steam navigation achieved during the fifty years of Her Majesty's reign; a progress which must certainly be acknowledged to be extraordinary when we remember that, at the commencement of the reign, the late Dr. Lardner publicly offered to eat the first steamship which should cross the Atlantic, whereas nowadays we have vessels which make the passage in a few hours over six days, and a fuel consumption at sea of 1¼ pounds of coal per indicated horse-power per hour is not uncommon. The speaker alluded to the various improvements, such as the use of steel in the construction of both hulls, engines, and boilers, the adoption of high-pressure steam and triple compounding, &c., which have principally contributed to the remarkable results attained.

The first paper read was by the late Director of Naval Construction at the Admiralty, Sir Nathaniel Barnaby, and dealt with the important subject of the connexion between the Royal Navy and the merchant service. This paper was rather political than technical in its character. The author's main object was to support the Admiralty in their recently announced policy of so organising the mercantile marine as to increase the power of national defence. He pointed out that a fast and properly constructed mail steamer may be as efficient a factor in naval war as an ordinary cruiser costing a quarter of a million sterling; and that there are even certain services which the mail-steamer, by reason of her greater size and travelling power, can perform better than the cruiser. On the other hand, the great mass of our mercantile marine is now relatively weaker than it has ever been before against the attacks of an enemy; for in the wars of the last century such ships as the armed East Indiamen possessed a well-recognised fighting value, but nowadays warships are so specialised that the majority of merchant vessels possess no powers of resistance whatever. Sir Nathaniel Barnaby also called attention to the fact that the State makes provision annually for a reserve of seamen, who are drilled periodically and paid by it, and who are liable to be called out to serve in case of war; and he then proceeded to show how, by good organisation, the superior merchant-ships, if manned mainly by naval reserve men, could in case of war be immediately available for service in whatever part of the world they might chance to find themselves. At the present moment the Royal and mercantile navies are under the control of two different Departments of State, and by some strange perversity the First Lord of the Admiralty is almost the only great political officer of State whose name is not to be found on the long list of members of the Board of Trade. As a natural consequence there is no community of action between the two Departments, and no organisation at present exists by which the services of the better class of fast merchant steamers could be rendered instantly available in case of war. The author's cure for this condition of affairs is the creation of a Secretaryship of State for the Navy, so that the interests of the merchant shipping and the Royal Navy might be united, and a truly national marine formed. There is no doubt but that Sir Nathaniel Barnaby in reading this paper has called attention to a very serious set of evils, which may all be remedied by a little organisation and by co-operation between two of the Departments of State. Even if the Board of Trade did not see its way to help in the work, what is to prevent the Post Office authorities from backing up the Admiralty by declaring that they would in future give the preference for mail-carrying purposes to steamers which fulfilled the Admiralty requirements of speed, subdivision, and structural strength, and what is to prevent the Admiralty from assisting the Post Office to obtain a cheap and efficient mail service by granting moderate retaining fees or subsidies to such steamers, provided they were always manned with a due proportion of naval reserve men and trained officers, and provided also that in consideration of the yearly subsidy their services were to be always at the disposal of the State in case of war at a fixed rental to be arranged beforehand. A beginning has undoubtedly been accomplished in the arrangements recently concluded between the Cunard and the White Star Lines on the one hand, and the Admiralty and the Post Office on the other, but much yet remains to be done, and we earnestly trust that Sir Nathaniel Barnaby's paper may be brought under the serious notice of those upon whom will devolve in time of war the care of our mercantile navy and the protection of our food supplies.

M. L. de Bussy, the Inspecteur-Général du Génie Maritime in the French Ministry of Marine, read a short paper on the results of a series of trials carried out on a torpedo boat at progressive speeds, in which he called attention to the fact that there is a diminution in the resistance of the hull after a certain speed has been passed. This fact was, however, already well known to members of the Institution, the peculiar sinuosities, or humps, as they are called, on the speed and power curves of vessels tried at progressive speeds having been often discussed at previous meetings. When all the causes of resistance to propulsion are separately analysed and expressed by correct formulæ, the causes of these successive maxima and minima of resistance will no doubt be clearly intelligible.

Mr. J. H. Biles, the scientific adviser of the firm of Messrs. J. and G. Thomson, of Glasgow, read an interesting paper on the twin-screw torpedo boats, *Wiborg* and *El Destructor*, constructed by his firm for two foreign Governments. The author first gave full particulars of the dimensions of the boats and engines, and their performances. These vessels were considerably larger than the generality of first-class torpedo boats, the *Wiborg* being 142 feet 6 inches, and the *Destructor* 192 feet 6 inches in length. They are both minutely subdivided, the former being provided with 23 and the latter with 39 water-tight compartments, the object being, of course, to enable them to keep afloat as long as possible when exposed to the fire of machine guns. The paper is interesting as showing the most recent tendency in torpedo-boat design. Recent experience in this country and in France undoubtedly points to the conclusion that the older type of first-class boats, though useful enough for harbour defence, are of little or no avail for service at sea. Whether the latest types described by Mr. Biles will fulfil reasonable expectations in this direction is a question which can only be solved *ambulando*. It may be noticed as a curious instance of the skill of modern marine engineers in evolving enormous powers out of engines of limited size, that the *Destructor*, whose load displacement is only 480 tons, has developed over 3800 horse-power, and has made the run of 495 knots from Falmouth to Muros in twenty-four hours, which corresponds to a mean speed of 20·625 knots.

Mr. Dixon Kemp, a well-known authority on yachting matters, read an interesting historical paper entitled "Fifty Years of Yacht-Building," in which he traced out the gradual evolution of the English and American types of racing yachts from the commencement of the present reign down to the most recent times. The author brings out very clearly the causes which have led to the adoption of the relatively narrow and heavily lead-ballasted boats which have hitherto found favour on this side of the Atlantic, and the broad, shallow, centre-board yachts peculiar to the Americans. In view of the recent triumphs of the American type, as represented by the *Puritan* and *Mayflower*, an alteration has been considered desirable in the old tonnage rule which taxed the beam so severely. The Committee of the Yacht-Racing Association appointed to report on the subject have recommended the following rule:—

$$\text{Rating} = \frac{\text{Length of loadline} \times \text{sail area}}{6000}$$

The first outcome of the new rule is the Clyde-built yacht *Thistle*, the principal proportions of which contrast strongly with those of the now famous *Galatea*, as will be readily seen from the following figures:—

	Galatea.	*Thistle.*
Length of loadline	87·0 feet	85·0 feet
Beam extreme	15·0 ,,	20·3 ,,
Draught of water	13·5 ,,	14·1 ,,

It should be mentioned that in the case of the *Thistle* the depth of the hold is measured to the bottom of the keel, which is a hollow box intended to hold the lead ballast. The contests, which will doubless take place during the coming season, between the *Thistle* and some of the powerful American centre-board yachts, will be watched with great interest by yachtsmen. Whether a contest between a keel-yacht and one fitted with the centre-board is a satisfactory trial of merit is at least open to question. In this connexion it may be mentioned that a yacht like the *Mayflower* when sailing off the wind can effect a reduction of 10 per cent. in her immersed surface by housing the centre-board, an advantage which is manifest, especially in the case of light winds and slow speeds.

A subject of great importance with regard to iron and steel ships is the protection of their bottoms from corrosion. Mr. V. B. Lewes contributed a valuable paper on the nature and genesis of rust, and on the protection of plates from its effects. It seems now to be generally admitted that the corrosion which distinguished some of the earlier steel-built ships was due to the presence on the plates of mill-scale or black magnetic oxide of iron, which forms, with the metal of the plate, a powerful galvanic couple, and gives rise, in the presence of sea-water, to very rapid pitting or local corrosion. The action is, in fact, similar at the outset to that which takes place between metallic lead and its peroxide in the well-known Planté secondary batteries. At the present time, steel plates are always carefully freed from this magnetic oxide before being worked into the hulls of ships—a practice which has been attended with the best results. Mr. Lewes believes that the protective compositions of the future will be made by dissolving a good sound gum, not easily perished by sea-water, in a volatile solvent, care being taken that neither gum nor solvent give rise to any organic acids. Body will be given to this varnish by finely-divided metallic zinc, which can now be obtained in so fine a powder that it can be used as a pigment. When, in time, the varnish perishes, as it must do from the action of sea-water under pressure, the zinc will set up galvanic action with the hull-plates; but, being the more electro-positive of the two metals, it will corrode, and will thus protect the iron or steel plates. This paper does not deal with the much-vexed subject of anti-fouling compositions—a much larger subject, which the author reserves for a separate memoir.

Sir Nathaniel Barnaby read a second paper on the subject of fuel-supply in ships of war, which, together with a paper by Mr. Biles, on the comparative effects of belted and internal protection upon the other elements of design of a cruiser, apparently provoked more interest and discussion than any other communication made to the Institution this year. The ships to which Sir Nathaniel Barnaby alluded were the *Impérieuse* and *Warspite*, belted cruisers, for the design of which he was himself chiefly responsible. These vessels have lately been the subject of much adverse comment both in and out of Parliament. As originally designed, the armoured belt was intended to reach from a height of 3 feet 3 inches above the water-line to a depth of 4 feet 9 inches below it. The supply of coal on which this calculation was based was 400 tons, but bunker space was allowed for an additional supply of 500 tons. During construction various additions were made to the weights of the boilers and the armament, which in their turn involved an increase in the weight of hull, and the net result was that the total weight of each ship was increased by 415 tons. Moreover, the present Board of Admiralty have decided that war-ships are in future to coal up to their full stowage capacity; that is to say, in the case of the *Impérieuse* and *Warspite* 500 tons more fuel are to be carried than the designer allowed for. As a natural consequence, the addition of 915 tons to the total weight of each vessel has immersed these ships so deeply that the height of the armoured belt above water has been reduced from 3 feet 3 inches to a little under 1 foot, and there are not wanting those who declare that this circumstance greatly injures, if it does not totally destroy, their fighting efficacy. Sir Nathaniel Barnaby very successfully proved that the responsibility for the additions to the weights of the hull and machinery belongs to the then Board of Admiralty, and not to himself. He also demonstrated that the addition of the extra 500 tons of coal was a case of deliberate reversal of the policy of one Board by its successor, but, judging from the tone of the discussion, he failed to convince his audience that the original policy of calculating the immersion of the belt on a fuel-supply of 400 tons was a wise one.

Mr. Biles's paper, above referred to, on the armour question, was an interesting and useful attempt to solve a difficult problem. He commenced by taking, as the basis of a definite comparison, the latest type of British belted cruiser, viz. the *Aurora*, of 5000 tons displacement. This vessel has a belt 5 feet 6 inches wide, of which 1 foot 6 inches is above the load-line; the thickness of the belt is 10 inches, and its top edges are united by an armoured deck 2 inches thick, under which are placed all the vitals of the vessel. With this he compares a type of cruiser without any side armour, but protected by means of a plated deck, the sides of which curve down so as to join the bottom some feet below the water-line, the curved or sloping portions of the deck being covered with armour of the same horizontal thickness as the *Aurora's* belt. In making the comparison he assumes—

(1) That the length and draft of the proposed vessel are to be the same as in the case of the *Aurora*.

(2) That the displacements are to be the same in each case.

(3) That the costs are to be the same.

Mr. Biles claims that in design No. 1 the internally protected vessel would weigh less than the belted cruiser by about 210 tons; that it would cost nearly 40,000*l*. less; and that the designer would have the option, on the smaller displacement, of either increasing the thickness of the flat portion of the armoured deck by 40 per cent. amidships, or of adding about six-tenths of a knot to the speed, or finally of adding one 9·2-inch gun and two 6-inch guns to the armament.

In the case of design No. 2, where the displacements of the two types are equal, it is estimated that either a knot and a half might be added to the speed, or else that the thickness of the whole of the deck-plating might be increased by 44 per cent.

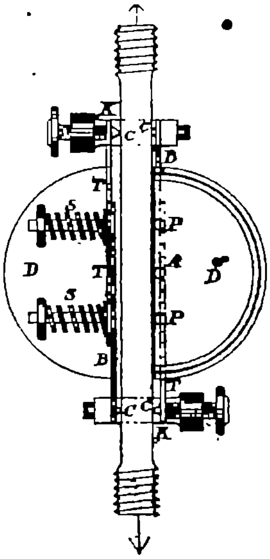
Lastly, on the assumption that the cost of the vessels is the same, Mr. Biles claims for the internally protected vessel the following important advantages: viz. 20 per cent. greater thickness of protection on the slope of the deck, 50 per cent. more on the flat, two more guns of the heaviest calibre, 20 per cent. more coal, and one knot additional speed. Mr. Biles very pertinently asks the question, Is the adoption of the belt worth the extra money paid for it with its accompanying sacrifices? or, If the money is to be spent, is the belt worth the sacrifice of speed, protection, and armament, which is entailed in its adoption?

The papers on marine engineering were not quite so interesting as some which have been read at recent meetings of the Institution. There were three on the subject of screw propellers, by Prof. Cotterill, F.R.S., Mr. Calvert, and Mr. Linnington of the Admiralty, and one on the machinery of small boats, by Mr. Spyer, also of the Admiralty. In addition to the foregoing there were two papers on stability, a subject which has been perhaps lately somewhat overdone; and an important contribution by Mr. Archibald Denny on the practical application of stability-calculations in relation to the stowage of steamships. Mr. Jenkins, the newly-appointed Professor of Naval Architecture at Glasgow University, prepared a paper on the subject of the shifting of cargoes.

STROMEYER'S STRAIN-INDICATOR

THIS is a very useful and ingenious apparatus for measuring the extension or compression produced on any material by tensile or compressive forces. Such deformations having been observed, the corresponding variation in the stresses to which the material has been subjected may at once be inferred by the ordinary law of elasticity connecting strains and stresses in solid bodies. The instrument affords one of the many examples of the valuable results obtainable by the simplest possible mechanical means—results which before the construction of the strain-indicator were considered altogether unattainable.

The instrument is shown in the woodcut, and consists of two flat plates, T, B, about 1½ inch wide and of any convenient length, pressed together by means of two springs, S, S, in such a manner that one plate projects at one end and the other at the other end. The plates are free to slide over each other at their ends opposite A. Fixed centre-points, C, C, are screwed one into each end of each plate, and a graduated dial, D, is attached to the upper one of the two plates T. Two of these instruments are held together by a pair of clamps, K, K, fixed just over the centre-points, which, when screwed tight, press the centres against both sides of the test-pieces; for safety against slipping, a few taps of a hammer embed them more firmly. The figure shows a round bolt about to be operated upon by tensile force, the screwed ends forming attachments to the grips of the testing-machine. Then, when everything is ready, a pair of very fine hardened steel wire rolling pins, P, P, to which light pointers have been attached, are inserted between the plates. These rolling pins, when in position, should be in the centres of the dials. On applying the load to the test-piece, elongation takes place; the centre-points move slightly away from each other, carrying the plates with them, which, as they move in opposite directions, and as they are held



apart only by the interposed rolling pin, cause it to revolve, and the angle through which it has moved can then be read off with the help of the pointer and dial. The best results have been obtained with a wire which was drawn, and which measures exactly ·015 inch in circumference. The dial is divided into fifteen equal parts, and their decimals, so that one division represents one-thousandth of an inch, and variations as small as a twenty-thousandth of an inch can be detected.

The above instrument is the outcome of another instrument invented by Mr. Stromeyer, of still greater sensitiveness, and which is based on the production of Newton's rings. Its extreme sensitiveness and certain practical difficulties, however, make it unsuitable for the use of the engineer or naval architect, to whom the present instrument is of great value, and by whom it can be very conveniently used.

The strains of a ship in a sea-way have always been very difficult to deal with. Agur and Solomon of old frankly admitted they were "too wonderful" for them, and although the same ingenuousness has not always been practised by naval architects since, the fact remains that the present state of knowledge in this subject is extremely meagre. Methods of calculation have, it is true, been in use by naval architects which have given results most useful for comparative purposes, but which in absolute units frequently indicated forces that ships could not bear. These methods therefore, except for the comparative purposes they were primarily designed to serve, threw no light whatever on the actual conditions of stress on the various parts of the structure in a sea-way. One able investigator showed that the dynamic constitution of sea-waves was such as to make the effective variation of buoyancy enormously less than the apparent variation, and that this difference meant a reduced variation of stress in large ships from, in some cases, 170 to 100. This investigation cleared up many pre-existing difficulties. Mr. Stromeyer, however, by means of his beautiful and simple apparatus, enables the variation of stress on any part of any structure, ship, or anything else under the action of any forces to be arrived at with certainty by direct experiment.

The invention of this little apparatus constitutes an era in the science of the strength of complicated structures such as ships, boilers, &c.

WILLIAM BABCOCK HAZEN

THE sudden death of Brigadier-General William B. Hazen, Chief Signal Officer of the United States Army, which occurred on Sunday, January 16, 1887, deprived the country of one of its most distinguished officers, and the Signal Corps of a chief who took a broad view of its duties and relations to the world of business and science.

General William B. Hazen was the great-grandson of Thomas Hazen, who was born 1719. Thomas Hazen was himself great-grandson of Edward Hazen, who emigrated from England before 1649, and settled at Rowley, Mass., where he died in 1683.

The descendants of Edward Hazen include many names eminent in business, theology, and war: energy, industry, and strong convictions characterise the members of the family on all sides.

General Hazen was born at West Hartford, Vermont, September 27, 1830. While he was a child his parents removed to Hiram, Portage County, Ohio. In 1851 he was appointed from Ohio as a cadet to the United States Military Academy, at West Point, from which he graduated on July 1, 1885. He was assigned to the 8th U.S. Infantry, and spent the next five years in frontier service, more especially against the Indians in California, Oregon, and Texas, in which service he displayed an energy and bravery that have been characteristic of his life. His record during these years embraces constant fights and pursuits. He was twice severely wounded, and by virtue of the latter he was, in January 1860, by the surgeon's order, granted a leave of absence as being unfit for duty. In consequence of this he was at the north while his regiment was in Texas at the breaking out of the Rebellion. The regiment having been captured and its officers released on parole, he alone was unembarrassed by the parole and was able to offer his services to the Union Army; he was at once assigned as temporary instructor at West Point. In May 1861, he became captain of the 8th Infantry of the regular army, and in October was made colonel of the 41st Regiment of Ohio Infantry in the volunteer army. During the war he distinguished himself on many occasions, and his commission as major-general was granted him December 13, 1864, for "specific distinguished services," *i.e.* "for long and continued services of the highest character, and for special gallantry and service at Fort McAllister." This placed him fifth in a list of twenty-four officers who had received commissions for distinguished service.

He continued serving on the frontier territories north and west, and was especially active in Indian affairs until 1870, in which year he was allowed leave of absence to visit the seat of war in Europe. The results of his observations and studies during his six months' absence are embraced in a volume entitled "The School and the Army in Germany and France, with a Diary of Siege Life at Versailles" (New York, 1872). This volume contains a very interesting sketch of Bismarck, and an account of the state of affairs in Europe. It contains especially a fair criticism of the relative excellencies of the German and French systems, both civil and military; in a special chapter on that subject he incidentally brought out more prominently some weak points in our own military organisation. It would seem that the courage displayed so brilliantly on the battle-field frequently nerved him to utter not only these but other fearless criticisms of things that were palpably wrong, and some of which have since been corrected.

He was married, February 15, 1871, to Millie, daughter of the Hon. Washington McLean, of Cincinnati, who, with one son, survives him.

On his return from Europe in 1871, he returned to duty in the Indian Territory, and was with his regiment in Kansas and Dakota, except for a short absence, until December 15, 1880, when he was, by President Hayes, appointed Brigadier-General and Chief Signal Officer, and has since then been stationed at Washington. The absence just referred to was occasioned by his again visiting Europe as Military Attaché to the United States Legation at Vienna, for the purpose of studying the operations of European armies during the Turko-Russian War. He was absent on this service from December 1876 to June 1877, and the results of his observations were published subsequently in a highly interesting popular volume.

The general account of his activity during the war of the Rebellion was published by him in his "Narrative of Military Service" (Boston, 1885).

His letters and pamphlets on the "Bad Lands" show that for many years General Hazen had been studying the relations of meteorology and agriculture. After his appointment as Chief Signal Officer, he was indefatigable in his efforts to improve the military and departmental relations of the Signal Service, its scientific character, its practical usefulness to farmers and herders, and its popular influence. His labours in Washington stirred up most virulent opponents, first when it became necessary for him to expose and prosecute the corruption of Capt. Howgate; again, when it became necessary in self-defence to expose the true reasons of the failure of the War Department to properly support and succour the Signal Service Expedition to Fort Conger; and again, when he had occasion to defend the advantages of the military character of the combined Signal Service and Weather Bureau organisation against those who would take it from the army without making a proper provision for its work in any other Department. The records of his successful defence against attacks prompted by implacable hate, official stubbornness, and personal ignorance, are to be found in the proceedings of "Courts-Martial," "Courts of Inquiry," "Committee of Congress on Expenditure," and especially in the "Testimony before the Joint Commission to consider the present organisation of the Signal Service," &c., which latter voluminous report and testimony was presented in June 1886.

General Hazen's interest in meteorology, as before said, properly dated back earlier than 1873, at which time he prepared a letter "On our Barren Lands, or the interior of the United States, West of the 100th Meridian, and East of the Sierra Nevadas." This was published in the *New York Tribune*, February 27, 1874, and led to a discussion in that paper and in the *Minneapolis Tribune* between himself and General A. A. Custer, which is summarised in a pamphlet of the above title, published by Robert Clarke and Co., of Cincinnati, in 1875. The motive of General Hazen evidently was the protection of investors and settlers against the too glowing accounts, which amounted to virtual misrepresentation on the part of the *employés* of the Northern Pacific Railroad. His compilation of climatological data, and his statement of personal experience based on long residence in that region, largely contributed to prevent blind emigration into an inhospitable country, while they doubtless also contributed to direct attention to the really valuable portions of our north-west territory, so that the permanent development of that portion of the United States has been furthered by his action. It was, however, at the time, on his part a very characteristic outspoken exposition of what seemed to him a fraud and imposition perpetrated by unscrupulous financiers upon foreign immigrants and over-confiding settlers and investors.

During his connexion with the Signal Office, General Hazen frequently took occasion to show his appreciation of the fact that the weather predictions were essentially not a matter of mere military routine, but that in all its details the office had need of the work of specially trained experts, that it was a mistake to shut one's eyes to the fact that, in a matter of applied science like this, some of those whom the scientific world recognises as meteorologists and physicists must be employed, and be required to keep the chief fully informed of the progress of science. Perhaps this is best exemplified by a quotation from his letter of March 24, 1886, addressed to a Committee of the House on Expenditures of the War Department:—"At the beginning of the work of the Signal Service the duty of giving notice of the approach and force of storms and floods for the benefit of commerce and agriculture throughout the United States implied that the notices should be correct, reliable, and timely, as none others could possibly be of benefit; it was therefore absolutely necessary to provide for the careful study of the atmosphere. On my accession I found every evidence from popular criticism that still further progress in weather predictions was expected. I therefore emphasised especially the necessity of the study of the instruments and methods of observing, and the investigation of the laws of the changes going on in the atmosphere. . . . It is evident by these successive steps that in addition to knowledge gained for current work the office is powerfully contributing towards the establishment of a deductive science of meteorology which will eventually give us a solid, rational basis for predictions, thereby improving on the empirical rules by which predictions have generally been made hitherto." And he adds that he was led more especially to assist in the researches on the sun's heat by reason of the encouragement given him by the late President Garfield, whose "last words to me were, 'Give both hands of fellowship and aid to scientific men.'"

As a further illustration of General Hazen's appreciation of the scientific needs of the office must be noted his appointment of Prof. William Ferrel as meteorologist, and of Prof. T. C. Mendenhall as electrician. To the latter, all matters relating to standards, instruments, and instrumental research were also committed. Nor did General Hazen stop here; by appointing several younger men to positions as junior professors he largely increased the amount of study and research that the office was able to perform, and by publishing a series of professional papers and smaller notes, he took the final steps necessary to stimulate every man to do his best.

Labouring in this same direction, he sought to elevate the intelligence and scientific training of the Signal Corps proper by enlisting College graduates as far as possible, by extending the course of instruction for observers, and by establishing a course of higher instruction for commissioned officers.

In still another direction General Hazen showed his devotion to scientific interests, namely, by his desire to conform as thoroughly as possible to the recommendations of the International Meteorological Conferences. These recommendations, as soon as received in the printed Minutes of the Conferences, were, by General Hazen's orders, carefully examined, and instructions at once prepared calculated to introduce methods of observation and publication in conformity with the recommendations of the leading meteorologists of the world.

Among the items specially noteworthy wherein General Hazen developed new paths of activity for this service, may be especially mentioned the study of local storms: first, tornadoes, which were especially assigned to Prof. Hazen so far as a collection of general statistics is concerned, and to Prof. Mendenhall so far as concerns the electrical phenomena proper. The study of atmospheric electricity was especially authorised, in 1884, by an order of the Secretary of War transmitting the resolutions of the International Electrical Conference held in Paris the preceding year. After full consultations with numerous electricians throughout the country, General Hazen decided that a daily map of electric potential showing lines of equi-potential similar to the iso-barometric lines, offered hopeful prospect of eventually leading to a method of predicting the formation and motion of thunderstorms and tornadoes. But the methods of observation and the apparatus needed first to be determined upon after careful experimental work. This whole matter was, therefore, in 1885, committed to the hands of Prof. Mendenhall.

Perhaps the most important item in internal administration, so far as it affects the permanent scientific value of the office work, was the effort heartily furthered by General Hazen to improve the accuracy and international comparability of our instrumental equipment. The standards of the International Bureau of Weights and Measures were recognised by him as being the proper legal standards for this office, and every effort was made to determine the corrections needed to reduce the past as well as the current meteorological observations of the office to agree therewith.

Perhaps the generous breadth of General Hazen's views, the absence of injurious jealousies, and his confidence in the principle that the Weather Bureau would be strengthened by the widest diffusion of an intelligent appreciation of meteorology, are in nothing more clearly shown than in the earnestness with which he stimulated the formation of State weather services and encouraged the study of meteorology in every school and college. He was painfully impressed by the disastrous influence upon individuals and business of the widespread and utterly absurd predictions of the storms and weather of

March 9, 1884, which were distributed broadcast throughout the country, and emanated from Mr. Vennor. He saw clearly that all this harm could only be prevented by increasing the intelligence of the people in scientific matters, and heartily indorsed every effort to diffuse a more correct idea as to what constituted legitimate meteorology.

Although his duties demanded the maintenance of a great central office at Washington, yet General Hazen realised that centralisation could easily be carried too far in scientific matters, and would thus react injuriously upon the work of his office. He was desirous of rapid progress in all directions, and, to secure this, welcomed every prospect of co-operation with other institutions as well as with individuals. One of his first acts was the request for co-operation on the part of the National Academy of Science. He improved the opportunity to help Prof. Langley in the determination of the absorbing power of the atmosphere; he accepted Prof. King's offer to carry observers on his balloon voyages; he heartily furthered Lieut. Greely's efforts to maintain an International Polar Station, and joined with the Coast Survey in establishing a similar station under Lieut. Ray at the northern point of Alaska; he co-operated with the Bureau of Navigation in securing weather reports from the ocean; he powerfully assisted the Meteorological Society in its labours for the reformation of our complicated system of local times, the result of which was the adoption by the country of the present simple system of standard meridians one hour apart.

Equally successful was he in his efforts to co-operate in various methods of disseminating and utilising the knowledge obtained by the Weather Bureau for the benefit of the business interests of the country. With the telegraph companies he published the daily telegraph bulletin. Through the railroad companies, he displayed the railroad train-signals visible to every farmer along the railroads. With local Boards of trade and other business interests he elaborated our system of flood warnings in the river valleys.

General Hazen was especially clear in his views as to the importance of giving personal credit to each man for his own personal work. Routine work was credited to the assistants in charge and not to the impersonal office. Having assigned a special work to the best man available, he took pains to give him the credit and make him personally responsible for its success, thus securing more enthusiasm in the work.

This notice of a few prominent features in the intense activity of General Hazen's life seems eulogistic rather than historical; but the fact is that military life rarely offers a position that requires the promotion of any special science, and still more rarely do official or military circles present an officer who so thoroughly desired, as far as allowable, to relax stringent military law and liberally interpret cumbersome official regulations, so that scientific men might successfully promote their special work.

Washington, February CLEVELAND ABBE

SIR WALTER ELLIOT, K.C.S.I., LL.D., F.R.S.

BY the death at an advanced age of Sir Walter Elliot, we lose one of the few survivors from a group of men who, in the second quarter of the present century, by their contributions to the zoology of British India, laid the foundations of our present knowledge. The subject of the present notice was, however, so widely known for his acquaintance with the history, coins, languages, and ancient literature of Southern India, that his zoological work might easily be overlooked.

Sir Walter Elliot was born in 1803 at Edinburgh. He was the son of Mr. James Elliot, of Wolfelee, Hawick, Roxburghshire, and after being educated at Doncaster, and later at Haileybury, where he received a "highly distinguished" certificate, he entered the East India Company's Madras civil service in 1820. In that service he held many posts of distinction. From 1822 to 1833 he was assistant to the political agent of the Southern Mahratta country, and during this period he collected the information subsequently embodied in his Catalogue of the Mammalia inhabiting the region, and also commenced the series of archæological studies, some of the first-fruits of which in 1836 were presented to the Royal Asiatic Society in the shape of a paper on Hindu inscriptions. With this paper were sent two manuscript volumes containing copies of no less than 595 sculptured records from the Southern Mahratta country and the neighbouring territory.

In 1837 he was private secretary to Lord Elphinstone, then Governor of Madras, and he was subsequently for twelve years a member of the Madras Board of Revenue. The value attached to his linguistic knowledge was shown by his being at one time Canarese translator, and at another acting Persian interpreter to the Government. From 1849 to 1854 he was Commissioner for the Northern Circars. During this period he made the collection of Cetacea subsequently described by Sir R. Owen in the Transactions of the Zoological Society, vol. vi. Finally he was Senior Member of Council in Madras from 1854 to 1859, when he retired from the service, and returned to pass the remainder of his life at Wolfelee, the residence of many generations of his ancestors. Almost his last official act in India was, when in charge of the Madras Government in 1858, to take the principal part in the transfer of the Presidency from the rule of the East India Company to the direct government of the Queen. He was created a K.C.S.I. in 1866, and became a Fellow of the Royal Society in 1878, and he was Deputy-Lieutenant of his county.

In his retirement his attention was much given to numismatics, and despite the complete loss of his eyesight in his later years, he carried to completeness the studies commenced in his "Numismatic Gleanings on South Indian Coins," published in the *Madras Journal of Literature and Science* for 1857. He brought out in 1885, with the aid of Mr. Thomas, General Pearse, and other friends, a general work on the "Ancient and Mediæval Coins of Southern India." Up to the very last his interest in Oriental literature remained unabated. One of his friends received a letter signed by him and dated March 1, the day of his death, containing inquiries as to the forthcoming edition of a Tamil work, and suggesting that the attention of Madras native students should be bestowed upon the early dialects of their own language. During the last ten years numerous notes by Sir W. Elliot have appeared in the *Indian Antiquary*, the latest in the September number of last year. Largely through his efforts the Amravati sculptures, now in the British Museum, were added to the national collection, and this was but one of the valuable additions due to him. His Southern Indian coins, a very large and important series, were presented to the same institution; and his numerous zoological collections enriched the Natural History Museum.

Although his published papers on zoology give but an imperfect idea of his contributions to the science, for many of his observations were freely communicated to other naturalists, and published by them, his "Catalogue of the Species of Mammalia found in the Southern Mahratta Country," which appeared in the *Madras Journal* for 1842, was of unusual merit. It had the peculiar advantage that it was a list, not of museum specimens, but of the wild animals inhabiting the country, several of which, and indeed nearly all the smaller rodents, were discovered by the author. The habits of the larger animals were described from personal observation, not, as has so frequently been the case, from information derived from native collectors.

Personally, Sir Walter Elliot was one of the kindliest of men, with a charming manner and generous disposition. At Wolfelee, as formerly in India, he was widely known and universally respected. W. T. B.

NOTES

He must be a very dull Englishman whose imagination has not been touched by the assembling of the Colonial Conference, an event which may hereafter be seen to have marked the first stage in one of the greatest movements in the history of mankind. In describing the commercial relations of the colonies, Sir Henry Holland, in his opening speech as President, had occasion to bring some very eloquent figures to the notice of the Conference. The imports and exports of the colonies were, in 1885, eleven times what they were in 1837. The British shipping trade with the colonies rose from 3,700,000 tons in 1837 to 56,600,000 tons in 1885, while, in the same period, British exports to the colonies rose from 11,300,000*l.* to 54,500,000*l.* This astonishing material progress, accompanied by an increase of population from 4,204,700 in all the colonies in 1837 to 15,763,072 in 1881, would, of course, have been impossible but for the rapid development of physical science and the steadily increasing application of its principles to the methods of industry. And it is interesting to note that, of all the questions which the Conference will have to discuss, by far the greatest are those most directly connected with the results of scientific investigation—questions relating to the naval and military defence of the Empire, and to the improvement of postal and telegraphic communication. In speaking of telegraphic communication, Sir Henry Holland quoted a striking letter he had received from Mr. Pender. Some of the facts brought together in this letter must have reminded the delegates very vividly of the debt which commerce owes to science. Twenty years ago there were only about 2000 miles of submarine cables, and some of the earlier cables were so badly constructed that they were practically useless. "Science has now, however," wrote Mr. Pender, "aided so greatly in the manufacture of cables that they can at the present time be laid with comparatively little risk of breakage and with an almost certainty of efficient repair." The consequence is that there are now 107,000 miles of submarine cables, which have cost something like thirty-seven millions sterling. The whole of this vast system, with the exception of about 7000 miles, is entirely under British control. To show the relative importance of the submarine cables, Mr. Pender stated that the length of all the land telegraphic lines now in existence in the world is about 1,750,000 miles, representing an estimated cost of 52,000,000*l.*

Dr. Brown-Sequard has been elected President of the Society of Biology, Paris. His immediate predecessor was the late M. Paul Bert.

A Bill was lately submitted to the U.S. Senate, providing for the creation of a Department of Agriculture and Labour. Various amendments were proposed, and among them was one for the transfer of the Weather Bureau from the Signal Office of the Army to the new Department. This amendment was accepted by the Committee on Agriculture, and *Science* says that it would certainly have been passed by the Senate had not difficulties unexpectedly arisen with regard to the Bill as a whole. The President, it seems, did not wish to have an additional member in his Cabinet. The Bill was therefore referred back to the Committee on Agriculture, and it did not again come before the House. According to *Science*, there can be no doubt that the Bureau will be transferred next year to some Civil Department, public opinion being decidedly in favour of the change. In the meantime General Greely, General Hazen's successor, will retain the position of Chief Signal Officer.

In the Report of the Scottish Meteorological Society, to which we referred last week, it is stated that during the winter Mr. Cunningham, Superintendent of the Zoological Laboratory of the Marine Station at Granton, and Mr. Ramage, have been continually engaged in a systematic study of the Chætopoda of the Firth of Forth. In the course of this work all the specimens obtained by dredging have been determined, and their anatomy has been investigated. Fresh specimens, and ova and young forms, have been collected on the shore at low tide, and by means of low nets; and a large number of drawings and descriptions have been made, among which are accounts of some species new to the district, and additions to the knowledge of anatomy and development. The results of this work are being prepared for publication.

The Report for the year 1884 of the United States National Museum, under the direction of the Smithsonian Institution, has just been issued. It contains (1) the Report of the Assistant Director, (2) Reports of the Curator and Acting-Curators, (3) papers based on collections in the Museum, (4) bibliography of the Museum for 1884, and (5) a list of accessions to the Museum in 1884. Among the papers based on collections in the Museum are two admirable anthropological studies by Mr. Otis T. Mason—one on throwing-sticks, another on the basket-work of the North-American aborigines. There is also an excellent study, by Mr. John Murdoch, of the Eskimo bows in the Museum. These papers are carefully illustrated.

On March 9 a Conference met in the Senate House, Cambridge, to discuss various questions in connexion with the Cambridge University Local Lectures. A report of the proceedings has been printed for the Syndics at the University Press, and it ought to be read by all who are interested in the subject of University Extension. Attention may especially be called to a speech by Dr. Westcott, who argued with much force that the affiliation of local centres to the University might provide an adequate foundation for a national system of higher education. Mr. Browne, Secretary of the Syndicate, who made a financial statement, set forth the claims of the movement to the support of all "who feel that the University Extension system has great powers for good, and has already done excellent work."

Science and Art, the first number of which has just been issued, deserves, and will no doubt receive, a cordial welcome from the class of readers to whom it appeals. Its principal object is to bring the schools of science and art into closer contact with one another. The articles, notes, and correspondence will be on subjects likely to be of especial interest to teachers in those schools, and it is also hoped that the journal may be of benefit to students. Each issue is to contain test-questions in science and art subjects, for which prizes of books and instruments will be given.

On Tuesday last Messrs. Mourlen, Belgian electricians, had an interview at Brussels with M. Granet, the French Minister of Posts and Telegraphs, relative to the establishment of a telephone line from Paris to London.

An excellent "General Guide" to the Natural History Museum, Cromwell Road, has just been printed by order of the Trustees. It contains plans and a view of the building.

Mr. T. B. Coombe Williams has compiled an interesting bibliography of the books, in his own library, on fancy pigeons. The authorship of the works in his list may, he says, be apportioned as follows: English writers, 58; German (including translations), 45; French, 21; Dutch, 3; Latin, 3; Italian, 5; Spanish, 1; Arabic, 1. More books on this subject have been printed in English and German than in any other language.

IN a recent Bulletin of the U.S. Fish Commission, Mr. J. W. Collins describes the finding of a knife of curious workmanship in the thick flesh of a large cod. The "find" was made at Gloucester, Mass., on September 15, 1886, by Capt. John Q. Getchell, when discharging a fare of codfish from his schooner. He had lifted several fish from a tub, and, running his hand over the thicker portion of one of them to call the attention of the by-standers to its fatness, he felt something hard beneath his fingers. Further examination produced a knife. The handle of the knife is of brass, curved and tapering posteriorly, with a longitudinal incision, on the concave side, to receive the edge of the blade. The form is remarkable, and suggests "the handiwork of some savage tribe, or the scrimshaw work of a sailor." The blade, which is of a lanceolate shape, has been corroded a good deal, and the extreme point is very thin. The total length of handle and blade together is 6¼ inches. "As to where the fish got the knife," says Mr. Collins, "we can only conjecture, unless some ethnologist can point out its origin. In any case, the finding of such a remarkable implement in such a strange place must be a matter of interest to the ethnologist and naturalist alike."

THE Colonial Council of Cochin China has decided to grant a sum of 6000 francs a year for life to M. Pierre, the Director of the Botanical Gardens at Saigon, provided he undertakes to finish in Paris the publication of his "Flore de la Cochinchine," and will leave all the manuscripts and collections which he has employed in the preparation of this work to the colony. The same body has granted La Société des Études Indo-Chinoises a subvention of a thousand francs to aid in the publication of its *Bulletin*.

WE have received the numbers of the *Essex Naturalist*, the journal of the Essex Field Club, for January, February, and March of the present year. The steady growth of the Club has led the Council to decide upon the issue of a monthly journal in place of the former Transactions and Proceedings at irregular intervals. It is scarcely surprising that residents of the county of Essex should appreciate the labours of the Society, inasmuch as they are wholly devoted to the county, and are of interest even to persons who know little of Essex. In this respect—namely, the thorough examination of the district lying at their doors—the members of the Essex Field Club set an example that similar Societies elsewhere would do well to follow. Anything relating to the natural history, geology, and prehistoric archæology of Essex is welcomed. Thus, amongst the papers in the three numbers before us, we have a discussion on a curious subsidence near Colchester in 1862; a report on the flowering plants in the neighbourhood of Colchester, by Mr. Shenstone, which is a kind of supplement for that particular district to Gibson's "Flora of Essex," published twenty years ago; notes on the saffron plant in England and its connection with the name of Saffron Walden; a paper on primæval man in the valley of the Lea, by Mr. Worthington Smith; and a paper on the deer of Epping Forest, by Mr. Harting. Apart from a succession of papers such as these, it is scarcely necessary to remind readers of NATURE of such excellent special work as Prof. Meldola and Mr. White's report on the East Anglian earthquake of April 1884, published by the Society. There are few associations in the United Kingdom which perform so adequately and thoroughly the proper functions of a local Field Club or Naturalists' Society, as the Essex Field Club.

EARTHQUAKES are reported from Travnik, in Bosnia, where a shock, lasting for five seconds, and followed by two others, was felt on March 22, about 3 a.m. On March 23 three shocks were noticed about 11.15 a.m. at Campfer and St. Moritz (Grisons). At Stuttgart, on March 25, about 4 a.m., a perpendicular shock was felt in the direction from west to east, followed by oscillations continuing for ten seconds. At Savona, in Italy, an earthquake was noticed about the same time. According to a telegram from Aden, dated the 5th inst., shocks of earthquake had been repeatedly felt there during the previous four days, but no damage had been reported.

MR. EDWARD WOODS, President of the Institution of Civil Engineers, will give a *conversazione* on Wednesday, May 25 (Derby Day). It will take place in the South Kensington Museum by permission of the Lords of the Committee of Council on Education.

THE semi-centennial anniversary of the University of Louisville was celebrated on March 2. The doctorate address on the occasion was delivered by Dr. David W. Yandell, who offered some interesting reminiscences of teachers of medicine in the University. When the institution was founded, it was the fourth medical school west of the Alleghanies. "There are as many schools now in Louisville alone," said Dr. Yandell, "as were then in all the territory which extended from the Ohio River to the Pacific Ocean." Dr. Yandell claimed on behalf of the University that it is "a school where practical medicine is taught in all its branches in a thorough, practical way." "It points to its record with becoming pride, and finds there its guerdon and its hope for the future."

ON April 1 the fine Botanic Garden of Glasgow passed from the hands of the shareholders of the Royal Botanic Institution into the possession of the Corporation of Glasgow. The Garden was founded in 1816. Shortly after this date the Botanic Institution received a Royal Charter, and in consideration of the importance of the teaching of botany in the University, as well as for the general encouragement of the study of this science, a sum of 2000*l*. was granted from the Treasury. A further sum of 2000*l*. was advanced by the University of Glasgow, on condition that special facilities should be given to the Professor of Botany in the University for teaching his science; and it need hardly be said that from this point of view the maintenance of the Garden is of primary importance. The financial history of the Garden has at no time been fully satisfactory, and the Institution has at the end of seventy years found itself in the position of a debtor to the Corporation to the extent of 46,000*l*. The greater part of this sum has been expended in recent years in the erection of fine conservatories, which, in point of condition and extent, place the Garden at the head of provincial establishments. The collections of plants date back to the foundation of the Institution, but the bulk of them have been acquired within the last ten years, very large and valuable donations having been received from Kew, Edinburgh, and Glasnevin, while large contributions have also been made by the leading growers throughout the country. Owing to peculiar municipal complications, following on the totally unexpected rejection of a Bill in Parliament for the annexation of Hillhead and Kelvinside to the city of Glasgow, by a Committee of the Lords, after it had passed through the House of Commons, it is as yet uncertain what line of action the Corporation may adopt with regard to this valuable property which has fallen into their hands. It is in their power to disperse the collections, sell the fine and costly houses, and dispose of the twenty-three acres of land for building-purposes. This course would be deplored not only by the citizens of Glasgow, who would thus lose for ever a most picturesque open space, but also by all who are interested in the botanical progress of the country. Were the establishment maintained on its present footing as a Botanic Garden, the Corporation would do credit to itself, and would materially assist in the advance of that which has always been the most generally popular of the sciences. Already the Corporation has shown that it is disposed to further botanical science by admitting students of the University to the Gardens under certain conditions, while the gates are locked to the general public. It is earnestly to be hoped that this may be the first step towards a permanent policy of encouragement of the study of botany in one of the most densely populated centres in the United Kingdom.

SOME of the American whitefish (*Coregonus albus*) turned into the waters of the Marquess of Exeter at Burghley Park a year ago, were lately caught. They were 7 inches long. This is important evidence as to their adaptability to English waters. The National Fish-Culture Association are incubating a large quantity of the ova of this species for acclimatisation purposes.

SINCE 1878 the Ontario and Western Railway Company has been engaged in re-stocking streams in America within the area of its route. Mr. J. C. Anderson, general freight and passenger agent of the Company, writes to the *American Angler* to the effect that, within the past nine years, 1,220,000 trout have been planted by the Company in the Beaverkill, Willowemoc, Neversink, the east and west branch of the Delaware, and their tributaries.

WE have received vols. xxxix. and xl. of the Proceedings of the Literary and Philosophical Society of Liverpool, containing the principal papers read to the Society during the Sessions 1884-85 and 1885-86. Among the papers of scientific interest in vol. xxxix. are: "Observations on the Nematocysts of *Hydra fusca*," and "The Relationship of Palæontology to Biology," by Mr. R. J. H. Gibson; "On a New Organ of Respiration in the Tunicata," and other papers, by Dr. W. A. Herdman; two papers on "Technical Education," by Mr. F. H. Edwards; "The Armorial Bearings of the Isle of Man, their Origin, History, and Meaning," by Mr. John Newton, and "On the Rocky Mountain Goat," by Mr. T. J. Moore. Vol. xl. contains an address on "Modern Scientific Theories of Man," by the President, Dr. William Carter; "Two Curious Papyri in the Khedivial Museum," by Mr. R. L. Benas; "Recent Locust Plagues in Cyprus and North America," by Dr. Nevins; and "Report on a Successful Importation of Living Soles to the United States," by Mr. T. J. Moore. With vol. xl. is bound "The First Report upon the Fauna of Liverpool Bay and the Neighbouring Seas," written by the members of the Liverpool Marine Biology Committee, and edited by Dr. W. A. Herdman.

THE additions to the Zoological Society's Gardens during the past week include two Macaque Monkeys (*Macacus cynomolgus* ♂ ♂) from India, presented respectively by Mr. W. Spooner and Mr. F. A. Adeney; a Purple-faced Monkey (*Semnopithecus leucoprymnus* ♂) from Ceylon, presented by Mr. W. H. Markham; a Black-tailed Godwit (*Limosa ægocephala*), British, presented by Mr. Robert Barclay; a Common Guillemot (*Lomvia troile*), British, presented by Mr. Howard Bunn; a Ring-hals Snake (*Sepedon hæmachates*) from South Africa, presented by Mr. W. L. Holms; a Pinche Monkey (*Midas œdipus*) from Central America, deposited; two Blue-bonnet Parrakeets (*Psephotus hæmatogaster*) from Australia; two Blue-crowned Conures (*Conurus hæmorrhous*) from Brazil, purchased; two Viscachas (*Lagostomus trichodactylus*) born in the Gardens.

OUR ASTRONOMICAL COLUMN

BARON D'ENGELHARDT'S OBSERVATORY.—Baron D'Engelhardt has recently published the first volume of the results of the astronomical observations obtained at his private observatory in Dresden. At first the observatory was erected in the Rue Leubnitz, but was found to be too far from the dwelling-house, and in 1879 the present edifice was erected in the Rue Liebig, close to the Baron's residence, with which it is connected by a covered gallery. The observatory is very completely fitted up. The principal instrument is a fine equatorial by Grubb of 12 inches aperture, replacing one of 8 inches which had been erected in the first observatory. There are two sidereal clocks, a chronograph, a transit-instrument of the bent form, which replaces one by Cook, a very complete Repsold micrometer, and two comet-seekers of special construction. The conduct of the screw of the Repsold micrometer has been very carefully investigated and the inquiry occupies a dozen pages. The observations are principally micrometer measures of nebulæ and star-clusters; but besides these there are very many observations of comets and minor planets, of the phenomena of Jupiter's satellites and of the new stars in the great nebula of Andromeda and near χ¹ Orionis, besides meridian observations of the moon and culminator stars. The volume, which is a very handsome one, contains four plates representing different parts of the observatory. The geographical position of the centre of the transit-instrument is given as lat. = 51° 2′ 19″ N., and long. = 0h. 54m. 54·74s. East from Greenwich.

NEW RED STAR.—Circular No. 16 of the Liverpool Astronomical Society states that on the nights of March 23 and 27 a red star, 7·5 magnitude, was observed 5s. *f* and 3′ *s* of 26 Cygni. There is no star in the D.M. at this place. The spectrum of the new star is a fine specimen of type III. Place of 26 Cygni for 1887, R.A. 19h. 58m. 9s., Decl. 49° 46′·9 N.

THE PARALLAX OF Σ 1516.—It appears, from the researches of M. O. Struve on the relative motion of the components of this double star, that the fainter star does not participate in the proper motion of the brighter component, and that they therefore, in all probability, constitute a merely optical pair without physical connexion. Herr Berberich, from a discussion of a series of measures of distances made by Prof. Winnecke, found the relative parallax of the brighter star, compared with the fainter component, to be 0″·199 ± 0″·05 (*Astron. Nachr.*, No. 2624). Recently, Dr. L. de Ball has made a series of observations with the equatorial of the Cointe Observatory at Liège, extending from 1885 April to 1886 June, for the purpose of determining this quantity. From sixty-seven observations of relative position-angle he finds π = 0″·091, and from sixty-four observations of relative distance, π = 0″·112, and combining these according to their respective weights, π = 0″·104, with mean error ± 0″·008.

ASTRONOMICAL PHENOMENA FOR THE WEEK 1887 APRIL 10-16

(FOR the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is here employed.)

At Greenwich on April 10.

Sun rises, 5h. 18m.; souths, 12h. 1m. 21·4s.; sets, 18h. 45m.; decl. on meridian, 7° 56′ N.: Sidereal Time at Sunset, 8h. 0m.

Moon (at Last Quarter on April 15) rises, 20h. 34m.*; souths, 1h. 47m.; sets, 6h. 50m.; decl. on meridian, 11° 44′ S.

GEOGRAPHICAL NOTES

MR. GEORGE GRENFELL has recently made a successful ascent of the great Quango tributary of the Congo. In company with Mr. Bentley, in the steamer *Peace*, he succeeded in reaching the Kikunji Falls, the point at which Major von Mechow, descending the Quango from the south, was obliged to turn back in 1880. About six miles above the junction of the Kasai and the Quango they found another large tributary, the Djuma, entering the river from the east, which presented so great a volume of water that it was a matter of uncertainty which was the larger stream. A little beyond this the course of the Quango veered round, first south-south-west, and then west; at 4° 30′ S. lat. it had come back to its usual northerly course, and maintained it for the remainder of the journey. The Kikunji Falls (5° 8′ S. lat.) are about 3 feet high, and though insurmountable to the *Peace*, are said by Mr. Grenfell to be no obstacle to communication by canoes and small craft.

IN a letter from the Rev. W. G. Lawes, dated Port Moresby, January 20, it is stated that an Expedition is being equipped under the leadership of Mr. Vogan, the Curator of the Auckland Museum, with the intention of attempting, as soon as the rainy season was over, to cross South-East New Guinea, from Freshwater Bay to Huon Gulf.

THE April number of the Proceedings of the Royal Geographical Society is largely devoted to papers on Central Asia. First we have Mr. Delmar Morgan's account of Prjevalsky's journeys and discoveries in Central Asia. Mr. Morgan also contributes a translation in abstract of a recent lecture by M. Potanin on his journey in North-Western China and Eastern Tibet, which is followed by an account of the travels of Messrs. James, Younghusband, and Fulford in Northern and Eastern Manchuria. In this last will be found some welcome details concerning of the country not previously described.

ACCORDING to Dr. Hans Schinz, who has been recently in the Lake Ngami region, that lake is not dried up, though its dimensions are gradually decreasing. The River Okovango forms an extensive marsh on the north-west, which sends very little water a part into the lake during the dry season.

IN a paper by Dr. Ochsenius in the *Zeitschrift* of the Berlin Geological Society, on the age of certain parts of the South American Andes, are some details of geographical and ethnological interest. The author believes that the South American Cordilleras, or at least a portion of them, are no older than the Quaternary (as contrasted with the certainly older coast Cordilleras), and infers, therefore, that Lake Titicaca and the surrounding region must have been raised to its present elevation of about 13,000 feet within the historical period. Dr. Ochsenius therefore maintains that the enormous ruins of the old Inca city Tihuanaco on that lake admit of no other explanation than that these colossal monoliths were not worked at their present elevation, far less transported thither; it is incredible that the highly civilised Incas would have located their emporium on a tableland now almost uninhabitable. The author supports his conclusions by the fact that representatives of the Pacific fauna still live in Lake Titicaca.

NEWS of Herr G. A. Krause, who is now investigating the district between the Gold Coast and Timbuctoo, has reached Berlin. The traveller arrived at Woghodogho, the capital of Mosi, in October 1886. He obtained permission from the King of Mosi to continue his journey in a northerly direction to Duensa, on his way to Timbuctoo. He hoped to reach the former place in seventeen or eighteen days, to arrive at Sarafaram in four or five days more, and then to descend the Niger to Kabara, the port of Timbuctoo. Herr Krause describes the country between Salanga and the capital of Mosi as being perfectly plain at first, and then followed by a district of low hills and another plain. A day's journey north of Walawala, the traveller crossed the Upper Volta, the source of which lies probably in a north-easterly direction.

ON CERTAIN MODERN DEVELOPMENTS OF GRAHAM'S IDEAS CONCERNING THE CONSTITUTION OF MATTER[1]

II.

A QUARTER of a century has elapsed since Graham formulated his conceptions concerning the constitution of matter. I wish now to indicate, as briefly as may be, how these conceptions have developed during these five-and-twenty years.

The idea of the essential unity of matter has a singular fascination for the human mind. It may be that it has its germ in the persistency with which every mind, even that of a child, seeks to get at first principles. The most superficial reader of the history of intellectual evolution cannot fail to perceive how greatly it has modified and directed the development of scientific thought. The whole course of chemistry, for example, has been controlled by this fundamental conception. The half-educated student of to-day may smile at the notion of the transmutation of the metals which held such sway over the minds of the early alchemists, but the men who followed this "*Ignis fatuus*" with weary faltering steps, and who frequently sank under the burden of disappointed hope and the sense that to them it was not given to know the light, felt that this idea rested on a rational basis. They, like we, could give a reason for the faith that was in them. And yet no article of scientific doctrine has in these later times suffered greater vicissitude. Men's ideas concerning the essential unity of things must have received a rude shock when it was found that such a thing as water was not only complex, but was made of bodies strangely contrasted in properties; that the air was still less simple in composition; and that, as it appeared, almost every form of earth could, by torture, be made to give up some dissimilar thing. The brilliant discoveries of Davy, which made the early years of this century an epoch in the history of science, seemed to open out a vista to which there was no conceivable ending. The order of things was not towards simplification: it tended rather towards complexity. And yet Davy himself seemed unable or unwilling to push his way along the path of which the world regarded him as the pioneer. It may be that he was unable to shake himself free from the domination of the schoolmen, or that he unconsciously felt the truth of the principles to which his own discoveries seemed opposed. It is difficult otherwise to account for the tardiness with which he accepted the hypothesis of Dalton; even to the last the Daltonian atom had nothing distinctive to Davy beyond its combining weight. Davy never wholly committed himself to a belief in the indivisibility of the atom: that indivisibility was the very essence of Dalton's creed. In arguing with a friend concerning the principle of multiple proportion, Dalton would clinch the discussion by some such statement as "Thou knowest it must be so, for no man can split an atom." Even Thomas Thomson, whom I have already characterised as the first great exponent of Dalton's generalisation, was torn by conflicting beliefs until he found peace in the hypothesis of Prout and Meinecke that the atomic weights of all the so-called elements are multiples of a common unit, and which he sought to establish by some of the very worst quantitative determinations to be found in chemical literature. It is curious to note the bondage in which the old metaphysical quibble concerning the divisibility or indivisibility of the atom held the immediate followers of Dalton. Graham, however, never felt such trammels. To him the atom meant something which is not divided: not something which cannot be divided. With Graham, as with Lucretius, the original atom may be far down.

---

[1] The Triennial "Graham Lecture," given in the Hall of the Andersonian Institution, Glasgow, on March 16, by Prof T. E. Thorpe, F.R.S. Continued from p. 524.

Every philosophic thinker to-day has, I should imagine, come to be of this opinion. Not many years ago it was the fashion to maintain that Stas's great work had for ever demolished the doctrine of the primordial *ylé*, and that Roger Bacon's aphorism that "barley is a horse by possibility, and wheat is a possible man, and man is possible wheat," was henceforth an idle saying. Stas's work is a monument of experimental skill, and it has furnished us with a set of numerical ratios which are among the best determined of any physical constants. It may be that it demolished Prout's hypothesis in its original form, but it has not touched the wider question. Whether indeed the wider question is capable of being reached by direct experiments of the nature of those of Stas is very doubtful, unless the weight of the common atom is some very considerable fraction, say one-half or one-fourth, of that of the hydrogen atom. Dumas has, as you know, modified Prout's hypothesis in this sense, by assuming as the common divisor half the atomic weight of hydrogen, but there is no *a priori* reason why we should stop at this particular subdivision. The exact relation of Stas's work to Prout's law has, I think, been fairly stated by Prof. Mallet at the conclusion of his admirable paper on the atomic weight of aluminium, in the Philosophical Transactions for 1880 (vol. clxxi. 1033). Stas's main result, says Mallet, "is no doubt properly accepted if stated thus, that the differences between the individual determinations of each of sundry atomic weights which have been most carefully examined are distinctly less than their difference, or the difference of their mean from the integer which Prout's law would require. But the inference which Stas himself seems disposed to draw, and which is very commonly taken as the proper conclusion from his results, namely, that Prout's law is disproved, or is not supported by the facts, appears much more open to dispute. It must be remembered that the most careful work which has been done by Stas and others only proves by the close agreement of the results that fortuitous errors have been reduced within narrow limits. It does not prove that all sources of constant error have been avoided, and, indeed, this never can be absolutely proved, as we never can be sure that our knowledge of the substances we are dealing with is complete. Of course, one distinct exception to the assumed law would disprove it, if that exception were itself fully proved, but this is not the case. As suggested by Marignac and Dumas, anyone who will impartially look at the facts can hardly escape the feeling that there must be some reason for the frequent recurrence of atomic weights differing by so little from accordance with the numbers required by the supposed law." Prof. Mallet, in tabulating the atomic weights which may be fairly considered as determined with the greatest attainable precision, or a very near approach thereto, and without dispute as to the methods employed, points out that out of the eighteen numbers so given ten approximate to integers, within a range of variation less than one-tenth of a unit. And he then proceeds to calculate the degree of probability that this is purely accidental, as those hold who carry to the extreme the conclusions of Berzelius and Stas, and he finds that the probability in question is only equal to 1 : 1097·8. And he concludes that not only is Prout's law not as yet absolutely overturned, but that a heavy and apparently increasing weight of probability in its favour, or in favour of some modification of it, exists, and demands consideration.

It would be impossible for me to attempt to traverse the whole ground of this question which has been opened up during the past fifteen or twenty years. Even if I could claim the time and your indulgence, there is hardly the necessity for such a demand on your patience. Mr. Crookes, only so recently as September last, gave an admirably complete exposition of the present state of the case in his address to the Chemical Section of the British Association at the Birmingham meeting, and for me to go over the ground again with you would be simply to plough with Mr. Crookes' heifer. Some years ago Mr. Norman Lockyer, as you doubtless know, approached the subject from another point of view, and in his recent work, "The Chemistry of the Sun," you will find a summary of the evidence which the spectroscope has afforded us concerning the dissociation of "elementary" matter at such transcendental temperatures as we have in [illegible] the sun.

Now, when we pass in review all this evidence; when we reflect upon the mode of distribution of the elements, and especially their tendency to associate in correlated groups; when we bear in mind the absolute analogy which exists in the general behaviour and mode of action of the radicles which are confessedly compound with those which are assumed to be simple; when we have regard to the phenomena of allotropy, isomerism, and homology,—the mind insensibly appeals to the principle of continuity, and refuses to believe that the seventy and odd "elemental" forms, to which our processes of analysis have reduced all the kinds of matter we see around us, differ in essence from bodies which are known to be compound.

The connexion between the properties of the "elements" and the relative weights of their atoms, as developed by Newlands, Mendelejeff, Lothar Meyer, Carnelley, and others, has served to strengthen this conviction. The discovery that the physical and chemical properties of the elements are as periodic functions of their atomic weights, is unquestionably the most important generalisation we have had in chemical philosophy during the last five-and-twenty years. Its bearings upon the question of the origin of the "elements" have been worked out in the Presidential address I have already referred to. Mr. Crookes, like Mr. Lockyer before him, in seeking to apply to this question of the genesis of the elements the same principles of evolution which Laplace has already applied to the creation of the heavenly bodies, and which Lamarck, Darwin, and Wallace have applied to that of the organic world, is again appealing to the law of continuity. The mind which holds that Nature is one harmonious whole is fain to believe that the probability that the elements have originated by chance and are eternally self-existent is just as remote as that the animals and plants of to-day are primordially created things. I think in what I am now saying I may fairly claim to be reflecting the opinion on this matter of every philosophic thinker of to-day. Nay more, you must allow that the germ which has been kept alive for so many centuries, and which has come down to us through the brains of a succession of thinkers like Leucippus, Aristotle, Lucretius, Bacon, Newton, Dalton, and Graham, has become quickened and endowed by the light which modern science has shed upon it from all sides, with a vitality which will persist and strengthen.

Having thus traced the development of the idea held by Graham of the essential oneness of matter, let us spend the few remaining moments in considering, in the most general way, how the science of the last twenty-five years has worked out and extended his conceptions concerning the properties of the atom and its mode of motion.

The treatment which "the few grand and simple features of the gas," to quote Graham's phrase, have received at the hands of Clausius, Clerk Maxwell, Helmholtz, Sir William Thomson, and a score of workers in this country and on the Continent who have been actuated by their influence, has served to dispel much of the metaphysical fog which has enshrouded the notion of the atom, and to-day we are able to reason about atoms, as physical entities, having extension and figure, and of their number and dimensions and peculiarities of movement, with the confidence which is based on well-ascertained facts.

We have, of course, not yet attained to a complete molecular theory of gases. But we know the relative masses of the molecules of various gases, and we have calculated in miles per second their average velocity. The phenomena of diffusion indicate that the molecules of one and the same gas are all equal in mass. For, as was pointed out by Clerk Maxwell, if they were not, Graham's method of using a porous septum would enable us to seperate the molecules of smaller mass from those of greater, as they would stream through porous substances with greater velocity. We should thus be able to separate a gas, say hydrogen, into two portions, having different densities and other physical properties, different combining weights, and probably different chemical properties of other kinds. As no chemist has yet obtained specimens of hydrogen differing in this way from other specimens, we conclude that all the molecules of hydrogen are of sensibly the same mass, and not merely that their mean mass is a statistical constant of great stability (see art. "Atom," "Encyclopædia Britannica," 9th edition). This line of argument has, it seems to me, an important bearing upon a question which has been raised by Marignac, Schutzenberger, and others, and which has again been raised by Mr. Crookes in the address I have already referred to. Mr. Crookes thinks that it may well be questioned whether there is an absolute uniformity in the mass of every ultimate atom of the same chemical element, and that it is probable that our atomic weights merely represent a mean value, around which the actual atomic weights of the atoms vary within certain narrow limits, or in other words that the mean mass is a statistical constant of great stability. The facts of diffusion would seem to lend no support to such a supposition.

Graham was still living when Loschmidt published what Prof. Exner calls his "epoch-making paper" on the "Size of the Air Molecule." Although the numerical estimate which Loschmidt deduced from the mean free path of the molecules and their volume has now only an historical interest, it has exercised a profound influence on the development of molecular physics in demonstrating that in dealing with molecules we are dealing with masses of finite dimensions, and further that these dimensions are by no means immeasurably small. The very manner in which Loschmidt stated his conclusions was well calculated to rivet attention. He showed that these magnitudes, small as they are, are yet comparable with those which can be reached by mechanical skill. The German optician Nobert has ruled lines on a glass plate so close together that it requires the most perfect microscopes to observe the intervals between them; he has drawn, for example, as many as 4000 lines in the breadth of a millimetre, that is about 112,000 lines to the inch. Now, if we assume, with Maxwell, that a cube whose side is 1/4000 of a millimetre is the smallest volume observable at present, it would follow that such a cube would contain from 60 to 100 millions of molecules of oxygen or nitrogen, and if we further assume that the molecules of organised bodies contain on an average 50 "elementary" atoms it further follows that the smallest organised particle visible under the microscope contains about two million molecules of organic matter. And as at least half of every living organism is made up of water, we arrive at the conclusion that the smallest living being visible under the microscope does not contain more than about a million organic molecules. I could have wished, had time permitted, to have dwelt a little upon the intensely interesting questions which such a conclusion at once raises. In the article "Atom" in the present edition of the "Encyclopædia Britannica," from which I have quoted, you will find Clerk Maxwell points out its relation to physiological theories, and especially to the doctrine of Pangenesis. Molecular science, says Maxwell, "forbids the physiologist from imagining that structural details of infinitely small dimensions can furnish an explanation of the infinite variety which exists in the properties and functions of the most minute organisms."

In the year following Graham's death Sir William Thomson still further developed the modes of molecular measurement, and from a variety of considerations based upon the kinetic theory of a gas, upon the thickness of the films of soap-bubbles, and from the electrical contact between copper and zinc, he arrived at estimates which, although sensibly different from that of Loschmidt, are still commensurable with it. In a subsequent lecture to the Royal Institution, given about four years ago, he extended the lines of his argument and arrived at the conclusion that in any ordinary liquid, transparent solid, or seemingly opaque solid, the mean distance between the centres of contiguous molecules is less than 1/5,000,000 and greater than 1/1,000,000,000 of a centimetre. And in order to give us some conception of the degree of coarse-grainedness implied by this conclusion he asks us to imagine a globe of water or glass as large as a football to be magnified up to the size of the earth, each constituent molecule being magnified in the same proportion. The magnified structure would be more coarse-grained than a heap of small shot, but probably less coarse-grained than a heap of footballs (NATURE, vol. xxviii. p. 278).

Here I think we may leave the subject, at all events for to-night. I am painfully conscious that I have left unsaid much that ought to have been said, and possibly said some things that might well have been left unsaid. But my main purpose will have been served if I have succeeded in indicating to you Graham's position as an atomist, and in showing you how his ideas respecting the constitution of matter have germinated, and, like the seed which fell upon good ground, have borne fruit an hundredfold.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, March 17.—"On the Total Solar Eclipse of August 29, 1886 (Preliminary Account)." By Arthur Schuster, F.R.S.

The instrument intrusted to me by the Eclipse Expedition was similar to that employed in Egypt during the eclipse of 1882. The equatorial stand carried three cameras, one of which was intended for direct photographs of the corona, while the two others were attached to spectroscopes.

Photographs of the Corona.—The lens had an aperture of 4 inches, and a focal length of 5 feet 3 inches; giving images of the moon having a diameter of about 0·6 of an inch.

During the first minute of totality the corona was covered by a cloud, which was, however, sufficiently transparent to allow the brightest parts of the corona to show on the ten photographs exposed during that time.

During the remaining time, that is to say, during about two minutes and a half, the sky was clear, but there were clouds in the neighbourhood of the sun.

The time of exposing the photographs which had been fixed beforehand had to be altered in consequence of the uncertainty of the weather, and for this reason I can only give the actual times of exposures very approximately and from memory. One photograph on sensitive paper shows only little detail; but three photographs on glass were obtained, which, as regards definition, I believe to be equal to those obtained in Egypt. The approximate exposures were 15 to 20 seconds, 10 to 15 seconds, and about 5 seconds.

With the view of possibly increasing the amount of detail which it has hitherto been possible to obtain on the photographs of the corona, I have, on this occasion, given considerable attention to the different adjustments, so as to fix the cause which at present limits the definition, and I have come to the conclusion that, if we are to obtain better photographs of the corona, we can only hope to do so by means of a better mechanical arrangement for moving the camera.

Photographs of the spectrum of the corona were obtained by means of two instruments, one being identical with that employed at Caroline Island in 1883. This spectroscope has two prisms of 62° refracting angle, the theoretical resolving power being about 10 in the yellow. (The unit of resolving power is the resolving power which allows of the separation of two lines differing by the thousandth part of their own wave-length.) The slit of this spectroscope was placed so that it was tangential to the image of the sun formed by the condensing lens. One plate was exposed during the whole of totality. The results are good; a number of lines belonging to the prominences and to the corona are very distinct and can be measured with fair accuracy. The difficulty of measurement lies in the multitude of lines. I have measured at present between forty and fifty distinct corona lines between the solar lines F and H, and a number remain unmeasured.

A comparison between the photographs of 1882 and 1886 shows that, although the lines seem to be in the same position, their relative intensity has greatly altered. The strongest corona line during the last eclipse had a wave-length of about 4232; it is slightly but distinctly less refrangible than the strong calcium line at 4226.

The second spectroscope had its slit placed so as to take a radial section of the corona. It had one large prism giving a theoretical resolving power of 11·4; slightly larger therefore than the two-prism spectroscope.

The film was one prepared by Capt. Abney so as to be more sensitive in the green than the ordinary plates.

The photograph obtained is faint, but I believe will ultimately give good results.

A good drawing of the corona was obtained by Capt. Maling at the station occupied by Capt. Darwin and myself.

The plates were prepared by Capt. Abney, whose valuable help I have had in the whole of the preliminary arrangements.

March 24.—"Preliminary Note on the 'Radio-Micrometer,' a New Instrument for measuring the most Feeble Radiation."[1] By C. Vernon Boys.

The author considered that, if the thermo-electric power of a junction were properly utilised, a more sensitive instrument would be made than the bolometer, which depends on the change of resistance of a conducting filament with temperature. After showing the defects of the ordinary thermopile, he explained the construction of his instrument. A circuit is made of one turn of 1 square centimetre, of which three sides are thin copper wire, and the fourth is a compound bar of antimony and bismuth, each piece being 5 × 5 × ¼ mm., soldered edge to edge. This circuit is supported by a thin rod, to which is fastened a mirror, and the whole is hung by a torsion fibre, so that the circuit is in the field produced by a powerful magnet with suitable pole pieces.

---

[1] I have learnt that an instrument essentially the same in principle as the radio-micrometer was made and shown by M. D'Arsonval to the French Physical Society; it is hardly necessary to say that I was not aware of this before reading the paper.—C. V. B.

When radiant energy falls on the centre of the bar, the circuit is deflected, and the amount of the deflection measures the energy. The instrument supplies the most delicate means of detecting radiant heat yet made. For instance, the particular instrument made by the author—having proportions which he now knows to be not the best, and with the keeper on the magnet, so that the field was one of 100 units only—was capable of showing the heat which would be cast on a halfpenny by a candle-flame at a distance of 1168 feet, and as the sensibility is proportional to the strength of the field, it would be fully ten times as sensitive with the keeper off.

By calculation it may be shown that an instrument made with certain given proportions, which are easily obtainable, would be capable of showing a change of temperature of the junction of 1/100,000,000 of a degree of heat.

The author also showed a motor consisting of a cross of metal, the centre being antimony and the arms bismuth, to the ends of which are soldered four copper wires, whose free ends are joined by a ring of copper which rotates rapidly when the spark at the end of a blown-out match is held near it.

If the spark is held on the right-hand side of the north pole, the motor will start itself oscillating through angles which increase until it at last begins to revolve, which it will do indifferently in either direction. If the spark is held on the left-hand side, the motor at once stops.

This is interesting in that it is an electro-magnetic motor which goes, having neither sliding nor liquid contacts.

The author promises, shortly, a complete paper in which the best proportions for the various parts are given, and to show an instrument in which these proportions are employed.

Geological Society, March 23.—Prof. J. W. Judd, F.R.S., President, in the chair.—The following communications were read:—Notes on the structure and relations of some of the older rocks of Brittany, by Prof. T. G. Bonney, F.R.S. These notes are the results of a visit to some of the more interesting geological sections in Brittany, in the autumn of last year. The author is greatly indebted for information to the Rev. E. Hill, who took part in the summer excursion of the Société Géologique de France, and to Dr. Charles Barrois, who has for long been engaged in investigating the geology of Brittany. (1) The author briefly noticed the glaucophane-amphibolites and the associated schists of the Ile de Groix, which have been already admirably described by Dr. C. Barrois. (2) The next part of the paper treated of sections in the district about Quimperlé. (3) In this part of the paper were noticed the crystalline rocks of Roscoff, and (more briefly) the Palæozoic strata about Morlaix, with the mineral and structural modifications due to pressure and to the action of intrusive igneous rocks. The author pointed out that, in the latter case, the results either of pressure-metamorphism or of contact-metamorphism differ much from the crystalline schists, which, both in Brittany and elsewhere, are regarded as of Archæan age; and that here in the north at Roscoff, we have a series of banded gneisses, less modified by subsequent pressure than in the south, the structures of which are very difficult to explain on any theory of a "rolling out" of a complicated association of igneous rocks, but which are such as would naturally result from some kind of stratification of the original constituents. The result of the author's work is to strengthen the opinion which he has already expressed, that while the structures of some foliated rocks may be regarded as primarily due to pressure operating on suitable materials, the structure of others seems opposed to this explanation. At any rate the latter rocks appear to have assumed a crystalline condition with a semblance of stratification in Pre-Cambrian times; so that, whatever may be their genesis, they are rightly called Archæan gneisses and schists.—The rocks of Sark, Herm, and Jethou, by Rev. E. Hill.—In opening the discussion which took place after the reading of these papers, the President remarked on the value attaching to Prof. Barrois's work in Brittany, and on the interest of the observations made on the country by Prof. Bonney. The conclusions as to the Archæan age of the lower gneissose rocks would probably be generally accepted; but a question which must still be regarded as an open one was, whether foliation ever corresponded with original bedding. The supposed instances of unconformity and current-bedding depended on the assumption that such was the case. Mr. Becker, Mr. Rutley, and Dr. Hicks, also took part in the discussion.—Quartzite boulders and grooves in the Roger Mine at Dukinfield, by Mr. James Radcliffe. The statements made in this paper were discussed by Mr. W. W. Smyth, Prof. Boyd Dawkins, Mr. Blanford, and Prof. Bonney.

Royal Microscopical Society, February 9.—Annual Meeting.—Dr. Dallinger was re-elected President for the fourth time. We have already printed the remarks made by Dr. Dallinger in his annual address on the value of the new apochromatic lenses. Having dealt with this subject, he proceeded to record the results of experiments as to the changes of temperature to which the lower forms of organisms can be adapted by slow modifications. For nearly seven years continuous experiments and observations were made, with the result that several organisms had gradually become adapted to live and thrive under a high temperature. Commencing at the normal temperature of 60° F., the first four months were occupied in raising the temperature 10° without altering the life-history. When the temperature of 73° was reached, an adverse influence appears to be exerted on the vitality and productiveness of the organisms. The heat being left constant for two months, they regained their full vigour, and by very gradual stages of increase 78° was reached in five months more. Again a long pause was necessary, and during the period of adaptation a marked development of vacuoles was noticed, which again disappeared when it was possible to raise the temperature farther. The farther history of the experiments presented practically the same features—long pauses, vacuolation, slow advance—until at last the high temperature of 158° F. was reached, when the research was accidentally terminated. It is because it is so difficult to observe the effects of changes through a sufficient number of generations of larger animals that results obtained on the simpler forms are so valuable. Darwin distinctly insisted on the slowness of the process of adaptation. The organisms examined by Dr. Dallinger are incessantly multiplying by dividing, the longest interval being four minutes: half a million generations must therefore have been observed, giving the "countless generations" required. At the end of the series the organisms were found to be fully adapted to a change in the essential condition of life, sufficient to produce death originally.

March 9.—Mr. W. T. Suffolk, Vice-President, in the chair.—Mr. E. C. Bousfield exhibited photomicrographs of *Amphipleura pellucida*, to show what may be expected from the employment of Prof. Abbe's new lenses. The objective employed was a very fine 1/8 apochromatic homogeneous-immersion 1·4 N.A. He also exhibited photomicrographs of salicine crystals as viewed by polarised light, and the colours were purposely selected to test as severely as possible the capacity of the plate used—a Dixon's orthochromatic.—Dr. Crookshank exhibited two photomicrographs of flagellated Protozoa of the blood. These were taken with Zeiss's 1/18 homogeneous-immersion from a preparation stained with magenta. The amplification (1750) was obtained by enlargement from the original negatives. They illustrated the employment of the Eastman bromide paper, and the value of photomicrographs for teaching purposes. The flagella and the delicate longitudinal membrane were clearly demonstrated.—Mr. W. Watson exhibited and described the Watson-Draper microscope, which he had made on the designs of Mr. E. T. Draper. The microscope is an elaboration of the Watson-Crossley form, and the idea of the designer is "that when the object is on the stage, either it may be made to rotate in any direction, horizontal or vertical, round a fixed beam of light without the light ever leaving the object, or the stage may be kept fixed while the light is revolving round it in any direction, horizontal or vertical, always however remaining upon the object."—Mr. J. Mayall, Jun., described the Nelson model microscope exhibited by Mr. C. Baker.—Two papers were read: by Mr. G. Massee, on the differentiation of tissues in fungi; and by Drs. H. J. Johnston-Lavis and G. C. J. Vosmaer, on cutting sections of sponges and other similar structures with soft and hard tissues, and specimens of sections of sponges were exhibited of exceptionally large size.—An arrangement by Mr. W. A. Haswell was exhibited for mounting series-sections to the number of thousands on one disk for consecutive examination.

EDINBURGH

Royal Society, March 7.—Sir W. Thomson, President, in the chair.—The President read a third communication on the equilibrium of a gas under its own gravitation alone. He finds that a large part of his former conclusions has been anticipated by Mr. Homer Lane.—Sir W. Thomson also communicated a paper on Laplace's nebular theory, considered in relation to thermo-dynamics. In the light of thermo-dynamical principles, Laplace's theory is seen to be not a mere plausible hypothesis but a statement of actual fact.—Dr. Thomas Muir read part of a paper on the history of the theory of determinants, treating of authors from Hindenburg (1784) to Reiss (1829).—Dr. Muir also communicated papers on a class of alternating functions, and on the quotient of a simple alternant by the difference-product of the variables.—Mr. J. Aitken read notes on solar radiation, and on hoar-frost.—An account of researches on the influence of certain rays of the solar spectrum on root-absorption and the growth of plants, by Dr. A. B. Griffiths, was submitted by Prof. Crum Brown.

March 21.—Lord Maclaren, Vice-President, in the chair.—Prof. Nicholson read a communication on variations in the value of the monetary standard.—Mr. J. Y. Buchanan read a paper on ice and brine, and another on the distribution of temperature in the Antarctic Ocean.

PARIS

Academy of Sciences, March 28.—M. Janssen, President, in the chair.—On the calorimetric bomb and measurement of heats of combustion, by MM. Berthelot and Recoura. The improvements are described which have been made in this apparatus, originally invented by MM. Berthelot and Vieille for the purpose of measuring the heats of combustion of organic compounds. The method, already applied to slightly volatile substances and gases, may now be easily extended to all volatile compounds, and is consequently a universal method.—On aerial vortices, by M. D. Colladon. The author announces that he has succeeded in carrying out on a small scale the experiment alluded to in his note of March 3, demonstrating that in a fluid there may be set up a vortex with vertical axis and ascending movement.—On the variation of solubility of substances according to the amount of heat liberated, by MM. G. Chancel and F. Parmentier. The experiments here described show that to a solubility increasing with the temperature there does not necessarily correspond an absorption of heat, so that one of the relations established by M. Le Chatelier must be rejected.—Extracts from various reports of the local engineering service on the effects caused by the earthquake of February 23, communicated by the Minister of War. Among the results recorded at Nice were the fissures produced in the Barbonnet Hill running along its entire elevation almost vertically to the magnetic north pole.—The same earthquake as observed at Moncalieri, by M. F. Denza. The diagram is given which was traced by the seismograph (Cecchi system) at the Moncalieri Observatory.—On the latent heats of vaporisation of some very volatile substances, by M. James Chappuis. The process here applied to the study of the chloride of methyl, sulphurous acid, and cyanogen is based on the employment of the Bunsen calorimeter, by means of which may be determined with considerable accuracy the latent heats of ebullition at 0° under the maximum tension corresponding to the melting of snow. The mean results obtained were for the chloride of methyl, 96·9; sulphuric acid, 91·7; cyanogen, 103·7.—On the determination of the coefficient of self-induction, by MM. P. Ledeboer and G. Maneuvrier. The method here employed to determine this quantity consists of a new adaptation of those of Maxwell and Lord Rayleigh to a particular case in which the coefficient is too weak to produce an appreciable shock in the galvanometer. It possesses the advantage of dispensing with the use of the ballistic galvanometer, and of rendering possible the employment of an ordinary galvanometer with mirror.—A study of the alkaline vanadates, by M. A. Ditte. With a view to determining the place that vanadium should occupy in a classification of simple elements, the author here begins a study of the little-known metallic vanadates, taking first the vanadates of potassa: (1) VO_5,KO; (2) $2VO_5,KO$; (3) $3VO_5,2KO$, &c.—Double phosphate and arseniate of strontian and soda, by M. H. Joly.—On some ammoniacal combinations of the chloride of cadmium, by M. G. André. This subject, already treated by Croft and Hauer, is here resumed chiefly from the stand-point of the comparisons that it suggests between the three metals zinc, copper, and cadmium, whose oxides are soluble in ammonia.—Action of nitric acid on the solubility of the alkaline nitrates, by M. R. Engel.—On the metallic propionates, by M. Adolph Renard. Among the propionates here studied are those of aluminium, barium, calcium, cadmium, chromium, cobalt, copper, lithium, magnesium, manganese, lead, potassium, sodium, strontium, and zinc.—Age of the upheaval of the Montagne Noire, French Pyrenees, by M. A. Caraven-Cachin. This upheaval is regarded as comparatively recent, being referred to the beginning of the Upper Eocene. It is more recent than the profoundly dislocated Lutetian and Bartonian beds, but older than the Ligurian system.—On the dolmens of Enfida, Central Tunisia, by M. Rouire. For the first time a systematic description is given of this remarkable group of dolmens, about 800 of which are found concentrated in a space of some 250 hectares, disposed without any apparent order, at distances of from 10 to 50 metres from each other. All belong to a perfectly uniform type, consisting of a long horizontal slab resting on upright stones joined at right angles. Except in a few depressions of the ground, none are covered with heaps of earth or stones so as to form true mounds or barrows, and all that were examined had the entrance on the east or south-east side. Like those of Constantine (Algeria), they are all of small size, the vertical stones scarcely exceeding 1 metre in height, and varying from 0·20 to 0·25 metre in thickness. In the few that were opened, little was found except some human bones and very coarse pottery, now deposited in the Ethnographic Museum.

BERLIN

Physiological Society, March 11.—Prof. Munk in the chair.—Dr. A. Baginski communicated the results of his observations and experiments respecting acetonuria in children. He found that acetone was present in small quantities in the urine of healthy children, though not in all; and that in the case of fever attending any of a very wide range of diseases, the quantity of acetone present in the urine was increased. When children were affected with eclampsia, attended, as such disease mostly was, by serious disorders in the digestion, a larger proportion of acetone was regularly observed in their urine. In regard to the formation of acetone in the blood, experiments in feeding, on different sorts of animals, showed that it was not produced by carbo-hydrates, as might be conjectured from the composition, $CH_3—CO—CH_3$, but from the decomposition of albumen. A longer course of flesh food yielded a very considerable increase in the secretion of acetone, whereas during a course of feeding with farinose and fatty foods, the yield of acetone very rapidly declined, and at length ceased altogether. When a large deposit of albumen occurred in the animal body, after the period of lactation for example, no acetone was found in the urine, even though food rich in albumen was administered. No causal connexion between acetonous urine and eclampsia could be demonstrated either clinically or experimentally. In rhachitis, in which eclamptic attacks often occurred, no acetone was found in the urine, nor was the administration of large quantities of acetone, even though continued for a considerable length of time, found to produce any effect on the nervous system.—Dr. Frenzel produced a long series of zoological and anatomical preparations preserved in accordance with his method. The preparations were hardened by means of alcohol containing sublimate, and injected with glycerine. The glycerine injection was effected first with a more diluted and then with a more concentrated solution, to which a solution of sugar was added as an ingredient. The relative proportion of glycerine and sugar was determined by the nature of the object.—Dr. Blaschko demonstrated, by drawings and very beautiful microscopic preparations, the structure of the epidermis. Starting with the assumption that the final endings of the nerves of feeling must be sought in the layer of the epidermis and not in the cutis, he had studied the structure of the upper skin at the boundary between epidermis and cutis. He distinguished the main parts of direct feeling (the hairless parts of the skin) from the parts of indirect feeling (the hairy parts of the skin). The former possessed on the under side of the epidermis very beautifully developed grooves (*Leisten*) forming a reticular system with spiral longitudinal and transverse lines. The hairy parts of the skin were influenced in their structure by the hairs, which likewise stood in spiral series, and had but very indistinct reticulations in the intermediate spaces.

Physical Society, March 4.—Prof. von Helmholtz in the chair.—Dr. Pringsheim reported on a further research into the chemical action of light on mixed hydrogen and chlorine gas (*Chlorknallgas*). This investigation respected the peculiar inductive action of light observed by Bunsen and Roscoe, during which the formation of hydrochloric acid was not effected, although the mixture of chlorine and hydrogen absorbed light, and at all events became changed, seeing the further influence of the like quantity of light at the end of the induction produced a chemical combination of the gases. In a former research (*vide* NATURE, vol. xxxiii. p. 287), Dr. Pringsheim showed that during the inductive action of the light an increase of volume in the gas mixture took place. If by means of electric sparks he illuminated the gas mixture in a glass globe above water, and shut off by a water index, then, on subjection to the first and each following spark up to the fourth, there occurred each time only an increase of volume which rapidly passed away; with the fifth and following sparks the effect was an increase of volume succeeded by a diminution; the latter a proof that hydrochloric acid was now formed and absorbed by the water. The speaker demonstrated at length that the assumption of a thermic influence as the cause of the increase of volume was excluded. On the contrary, he argued, there could here be a case only of chemical change in the gas mixture. It was probably an intermediate condition we had here to deal with, which of course refused explanation from the contemplation of the two gases Cl and H. Seeing that aqueous vapour was also present in the glass globe, the part it played in the reaction was now examined, and the fact was established that its presence was absolutely indispensable in effecting the chemical light effect. Dry chlorine and hydrogen did not unite into hydrochloric acid under the influence of the light; or the process was in such a case effected only very slowly. In all probability, therefore, the induction would have to be explained on the ground that intermediate products with larger volume were formed from the molecules ClCl, HH, and HHO, products whose chemical nature it had not yet been possible to determine.—Prof. Neesen made some supplementary communications respecting the tuning-forks filled with quicksilver, and stated that they had been constructed at an earlier date by Herr Konig.—Prof. von Bezold described a simple method of presenting complementary colours by means of prism, lens, and a special screen.—Prof. Vogel produced three fluids in three flat phials—one yellow and two blue fluids—which he made use of in demonstrations regarding colour-mixture in order to dispel the belief which prevailed very largely amongst the public that yellow and blue when mixed yielded only green. Phial 1 contained "acid yellow" (*Sauregelb*); phial 2, solution of ammoniacal copper; phial 3, aniline blue. 1 and 2 superimposed on each other gave green; 1 and 3 a fiery red.

Chemical Society, February 14.—Prof. H. Landolt in the chair.—F. Tiemann gave an account of Kiliani's research, according to which arabinose-carboxylic acid has the same composition as gluconic and galactonic acids. Arabinose is regarded as an aldehyde of normal pentahydroxypentane.—Amongst the other papers may be mentioned:—A contribution to our knowledge of secondary and tertiary quinones, by R. Nietzki and F. Kehrmann.—Tetramidobenzene and its derivatives, by R. Nietzki and E. Hagenbach.—Substitution of the amido-group in aromatic compounds, by the groups SH and SO_3H, the change being effected by means of a new diazo-reaction, by P. Klason.—The six toluenedisulphonic acids, by the same.—The constitution of pyrene and its derivatives, by E. Bamberger and M. Philip.—The action of chlorine on acet-α-naphthalide, by P. T. Cleve.

February 28.—A. W. Hofmann, President, in the chair.—G. Kraemer gave an account of the work done by himself in conjunction with W. Bottcher on the constituents of mineral naphtha. They have examined naphthas from Tegernsee, Pechelbronn, and Oelheim, and find they consist of a mixture of hydrocarbons which are not acted on by concentrated sulphuric or nitric acid, and of such as are dissolved by the acids with formation of sulphonates and nitro-derivatives; also small quantities of acids. The indifferent hydrocarbons are distinguished by their low specific gravity; they constitute the greater portion of the naphtha, and they consist partly of paraffins and partly of hydrocarbons isomeric with the olefines; these are called naphthenes. The authors consider the non-aromatic hydrocarbons which are soluble in acid to be derived from the naphthenes by condensation, in the same way as naphthalene, anthracene, &c., are derived from benzenes. The authors also discuss the question of the origin of mineral naphtha.—Amongst the other papers may be mentioned:—J. W. Bruhl, on J. Thomsen's theory of the heat of formation of organic substances.—C. Gottig, on a new hydrate of soda.—Claisen and Lowman, on a new method of producing benzoyl-acetic ether.—A. Piutti, synthesis of trimesic ether.

A NATURALIST IN SOUTH AMERICA[1]

Notes of a Naturalist in South America. By John Ball, F.R.S., M.R.I.A., &c. (London: Kegan Paul, Trench, and Co., 1887.)

II.

LEAVING Valparaiso, and steering southwards amongst the evergreen islands of the South Chilian Archipelago and Fuegia, Mr. Ball encountered all the disagreeables of those inhospitable and desolate regions, signalised by a fall of the barometer and thermometer, gales of wind, the rolling seas of a tempestuous ocean, fogs, and darkness. And here he observes (and the observation is new to us) that one of the main features of the Andes suffers a great change. The western chain, which runs for 900 miles as an almost continuous range of high land on the coast of Chili, from lat. 40° S. to the Straits of Magellan becomes separated from the range to the east of it by a broad belt of low country including several large lakes. Further south the chain first dips under the ocean, to emerge as the great Island of Chiloe and the Chonos Archipelago, after which it joins the continent again at Cape Tres Montes. Further south is the Gulf of Peñas, forty miles wide, beyond which are the famous channels that lead into the Straits of Magellan. The new geographical features are accompanied by a change of climate, and this again is marked by the appearance of many types of the so-called Antarctic (or rather Fuegian) flora, which may be traced northward from Fuegia to the Mountains of Valdivia, and some few of which types, profiting by the fogs of the desert region of the Andes, straggle northwards into Northern Chili. In Messier's Channel, lat. 50° S., the wild celery of Europe was found, of which Mr. Ball says: "Growing in a region where it is little exposed to sunshine, it has less of the characteristic smell of our wild plant, and the leaves may be eaten raw as salad, or boiled, which is not the case with our plant until the gardener, by heaping soil about the roots, diminishes the pungency of the smell and flavour." "The 5th of June," he goes on to say, "my first day in the channel, will ever remain a bright spot in my memory. Wellington Island, which lay on our right, is over 150 miles in length, a rough mountain range, averaging apparently about 300 feet in height, with a moderately uniform coast-line. On the other hand, the mainland presents a constantly varying outline, indented by numberless coves and several deep narrow sounds running far into the recesses of the Cordillera. In the intermediate channels crowds of islands, some rising to the size of mountains, some mere rocks peeping above the water, present an endless variety of form and outline. That which gives the scenery a unique character is the wealth of vegetation that adorns this seemingly inclement region. From the water's edge to a height which I estimated at 1400 feet, the rugged slopes were covered with an unbroken mantle of evergreen trees and shrubs. Above that height the bare declivities were clothed with snow, mottled at first by projecting rocks, but evidently lying deep upon the higher ranges. I can find no language to give any impression of the variety of the scenes that followed in quick succession against the bright blue background of a cloudless sky, and lit up by a northern sun that illumined each new prospect as we advanced."

In another passage the scenery is compared to that of the Upper Lake of Killarney, where the evergreen beeches of Fuegia are represented by the arbutus; and where, Mr. Ball might have added, similar climatal features nurture a similar wild variety, profusion, and luxuriance of cryptogamic plants, mosses, ferns, and hepaticæ, and especially broad foliaceous lichens that grow nowhere else in the northern hemisphere in like number and variety. A further similitude between Fuegia and the south-west of Ireland may be traced in the rock-girt deep sounds that run far into the land of both, and which harbour a marine vegetation that has perhaps no parallel for variety, luxuriance, and beauty in their respective hemispheres.

The meeting with floating masses of glacier ice in Eyre Sound suggests some excellent remarks on the well-known phenomenon of the depression of the snow-line and of glaciers in this region, as compared with the northern hemisphere. Threading a devious course through the Straits of Magellan, Mr. Ball's enthusiasm rises to a white heat, that warms the land- and sea-scapes of the grim "Land of Desolation." In his eyes, Fuegia's midwinter glows with brilliant hues. It would make Magellan and Del Canot, Narbough and Davis turn in their coffins could they but read Mr. Ball's ecstasies over the features of the countries in which they starved and froze, and where so many of their ill-starred comrades left their bones, after their bodies had endured incredible sufferings. No doubt we may attribute much of the rapture experienced by our traveller to the contrast which the luxuriant vegetation and picturesque scenery of Fuegia presented to the dismal sterility of the Peruvian and North Chilian coasts, and more to the keen interest which he took in the botany of the region. Still, though "Tantus amor florum" may account for a good deal, there is a large measure of beauty in the scenery of Fuegia that he has been the first to analyse, appreciate, and describe with truth and picturesqueness. Take his picture of Mount Sarmiento, for example, a mountain 7000 feet high. "Sole sovereign of these Antarctic solitudes, I know of no other peak that impresses the mind so deeply with a sense of wonder and awe. As seen from the north, the eastern and western faces are almost equally precipitous, and the broad top is jagged by sharp teeth, of which the two outermost—one to the east, the other to the west—present summits of apparently equal height." Speculating on its geological age, he considers it evident that it is not of volcanic origin, for that no volcanic rock can retain slopes so nearly approaching the vertical. He regards it as a portion of the original rock-skeleton that formed the axis of the Andean Chain during the long ages that preceded the great volcanic outbursts that have covered over the framework of the western side of South America, and that in the course of upheaval its flanks have been carved by marine action to the nearly vertical form which impresses the beholder.

---

[1] Continued from p. 531.

After a short stay at Sandy Point, a Chilian settlement at the eastern mouth of the Straits, Mr. Ball proceeded to Monte Video and Buenos Ayres, from whence he ascended the Uruguay River; and, passing Fray Bentos, the great factory of "Liebig's Extract of Beef," finally reached Paysandu, equally familiar to English housekeepers for its preserved tongues. This digression gave him a fair view of the aspect of the flora of a great extent of the Argentine Confederation, which, with its Pampas, Salinas, and riparian vegetation differs wholly from that of all the regions he had hitherto visited. For the Argentine Confederation he proposes the term "Argentaria," a good one, which will, we hope, be acceptable to biologists, and to geographers too.

Santos, in South Brazil, was the next point visited, and from there Mr. Ball took the rail to Sto. Paolo, and thence on to Rio de Janeiro. Here he is upon ground familiar to naturalists, and we need only allude to the singular speculation to which his observations on the geology of that part of Brazil, and his reading of the observations of others on the same subject, have given birth. After dwelling on the enormous area of Brazil occupied exclusively by granite and gneiss, and the extent and depth of the deposits of the disintegrated materials formed out of the same matrix, including 200,000 square miles of the plateau of Brazil, the Argentine Pampas, and Paraguay, he goes on to say: "To my mind the conclusion is irresistible that ancient Brazil was one of the greatest mountain regions of the earth, and that its summits may very probably have exceeded in height any now existing in the world." And it is these mountains which he regards as the probable birthplace of the chief types of the phanerogamous vegetation of South America. A few peculiar types, indeed, may have been developed in the Andes, but not such as have stamped their features on the vegetation of the continent. Mr. Ball further correlates this speculation with another as bold, which he gave to the Geographical Society in 1879 (Proceedings, p. 464), and which is, that the chief types of existing flowering-plants originated in the higher mountain regions of the globe "at a period when the proportion of carbonic acid gas present in the atmosphere was very much greater than it has been since the deposition of the Coal-measures." To discuss these novel ideas would be out of place here; but we must, in justice to our author's candour, add his avowal that he regards them "as having no claim to rank as more than probable conjectures, but that, as they rest on some positive basis of facts, they may be serviceable to the progress of science by stimulating inquiry."

It remains to add that the work concludes with two appendixes—one "on the fall of temperature in ascending to heights above the sea-level," which is a model of painstaking research into the methods and observations hitherto adopted, but which leaves this complex subject no further advanced; the other, "on Mr. Croll's theory of secular changes of the earth's climate," is a really valuable contribution to that fascinating inquiry. And here we take leave of Mr. Ball, congratulating him heartily on having added to our library of South American travels a volume that well deserves a corner of the shelf that contains those of Humboldt, Darwin, and Bates.

PALÆOLITHIC MAN IN NORTH-WEST MIDDLESEX

Palæolithic Man in North-West Middlesex. By J. A. Brown. (London: Macmillan and Co., 1887.)

THIS work has two faults by no means peculiar to itself, but which it shares with many books on science.

One of these is the large amount of introductory matter that bars the way to the special subject of study. Thus we do not get into Middlesex until reaching page 42, and then we quit it again after p. 120, to return at p. 185. Certainly, our author shows us how much trouble he has taken in looking up authorities on palæolithic and savage man in general; but he should remember that some folk don't like their whisky to be over-watered.

The second fault one must allude to with sorrow. Why is it that so many scientific scribes have such a weakness for slipshod English? Is it that they feel the advance of science to be so rapid that their works will be passed by in a few years, as out of date, so that it is not worth while to cultivate style, and grammar is hardly essential? Or is it that they expect the bad language of to-day to be the good language of the future, by an evil process of evolution, the survival of the unfittest? Let Prof. Lankester note this as a possible case of degeneration.

One cannot resist giving some examples. On p. 11 we are told that "abundant traces of man in the Neolithic Age are found on the surface of the ground, which may be picked up on ploughed fields." The surface of the ground is usually a good deal picked up on ploughed fields; but of course that is not what is meant. An author who has written much on prehistoric man might perhaps be justified in bringing an action for libel for the remark on p. 67 that "the fauna—as Prof. Dawkins says—is the same, and are referable to the same geological horizon." On p. 90 it is said of a certain tool that "it certainly has the appearance of greater antiquity as an implement, than do a very large proportion," &c. In the middle of p. 94 three successive sentences begin with "It," but that awkward little word in two cases stands for one particular implement, whilst in the third the general type to which that implement belongs must be referred to, as the particular "it" cannot have been found, in these unmiraculous times, in three distinct places: at Ealing, in Kent, and in Surrey. At p. 112 the singular "No. 131" is shortly followed by the plural "They," the latter being meant to refer to other numbers as well.

Having said this much as to things in general, we may say that Mr. Brown's book is a praiseworthy account of a particular district, and that it would not be amiss if other districts had as careful an observer in their midst, eager to see every section, and to record every find. It is a work that London antiquaries and geologists should possess.

Up to the time when Dr. Evans's great work on stone implements was published, but few specimens of worked flints had been recorded from the metropolitan district; but in the same year, Colonel Lane-Fox (now General Pitt-Rivers) recorded the finding of a large number in the gravels round Ealing. Notwithstanding this, however, hardly any addition was made to London implements for some years, when Mr. Worthington Smith developed the marvellous faculty of finding them in nearly every gravel-pit he went into. Our author makes a good third to these two, and that is saying a great deal. It is to be hoped that his book may lead other observers to join in the work that he has so much advanced, and to do for other parts of London and the surrounding country what he and the above-named authors have done on the north-west and north-east, and Mr. F. Spurrell on the south-east.

The antiquity of man is so controversial a subject that anyone who writes on it must expect to find more foes than friends. Mr. Brown, therefore, must not be surprised at exception being taken to some of his views, and in noticing his work one may fairly point out some matters on which opinions are likely to differ.

The remark, on p. 13, of piles (for dwellings) having been found at Moorfields received a curious illustration whilst it was in the press; for a building in that district was then being underpinned, on account of part of the pile-structure on which it was based having decayed; that building being none other than the lecture-hall of the London Institution.

The name "chalky boulder clay" was given by Mr. S. V. Wood, Jun., and not by Mr. Skertchly, as the foot-note on p. 27 says.

That the brick-earths of Erith, Crayford, &c., are pre-glacial few geologists will be found to believe; perhaps, indeed, only Prof. Dawkins; and our author wisely throws the burden of this belief on that gentleman (p. 33).

As to the Tilbury man, alluded to on p. 42, there can be no doubt that his remains were found in a very late post-glacial deposit, simply the alluvium of the Thames. Mr. T. V. Holmes has set this question at rest (Trans. Essex Soc.).

By a slip, on p. 45, hard chalk, flint, and greywethers have been classed amongst rocks that do not occur in the valley of the Thames.

Probably there are geologists who would be disposed to question the strictly glacial origin of the furrowed gravel and the bent loam carefully described on pp. 45-47. Such irregular surface-deposits are so common in districts far from undoubted glacial beds as to leave their origin doubtful.

"The large encroachments of the sea which have taken place . . . in historic times" are no proof of depression (p. 48). They are simply the result of denudation along coasts.

The term "alluvium" should be confined to the deposits of rivers and not applied generally to surface-soil, as on p. 50, in which case it becomes a useless synonym.

The peculiar black bands often seen in gravels have troubled many observers, but from finding particles of carbonised wood occasionally in them Mr. Brown is not justified in saying that "there seems to be no doubt that such black strata are due to vegetable life," especially as he recognises the fact that the *colour* (which is what he refers to) is generally due to oxide of iron or of manganese. And even were the blackness due to vegetation, it is by no means a reasonable assumption that the beds were land-surfaces (p. 54), for the vegetable remains may have been carried down by water. That the white beds occasionally seen are "probably the result of decomposition of animal or vegetable matter" is also rather doubtful, the colour (which here again is what the author refers to, though his language implies the beds themselves) being often the result simply of the washing-out of the iron-oxide, which gives the usual brown tint, by percolating water.

There may be some doubt whether, when man first invaded England, the connexion of our country with the mainland was caused "by the uprise of the bottom of what is now the . . . North Sea." The present severance need not have been brought about by depression, but perhaps is owing simply to denudation, so that there is no need to invoke uprise to account for former connexion. There is also some difficulty in the uprise in question, as Mr. Brown thinks that Middlesex, &c., "was slowly emerging from the sea," and therefore must have been at a lower level than now. It is most likely indeed that at that time the whole land was higher than now, as otherwise it would be hard to account for the greater size of the rivers, as compared with their present descendants, for higher land would give greater rainfall, and greater rainfall means stronger streams. If "man beheld the land now under the 300-foot contour in Middlesex as an arm of the sea," there could have been nothing worthy the name of river, or even of brook, in the county, and the deposition of such coarse matter as our river-gravels would be out of the question (pp. 67, 68), those gravels certainly not being marine deposits.

In the picture of a Palæolithic scene from Castlebar Hill (pp. 185, &c.), it would seem as if the author were, as is often the case with geologists, a little too much impressed with the present features of the country, so as to allow too little for the amount of denudation that has happened since the time his picture represents. Instead of water then occurring over the whole of the low clay-country to the north, is it not possible that the tract in question was much higher than now, a great sheet of clay having been gradually swept off it since? Indeed, the author distinctly recognises the great amount of denudation that has occurred south of Castlebar Hill, along the valley of the Thames (pp. 191, 192), and of course there is no possibility of the process being confined to one side of the ridge.

The conclusions of Dr. Hicks as to the Glacial or pre-Glacial age of man in North Wales, noticed at the end of the work, are not altogether accepted, and should be considered as still waiting for the verdict of geologists.

Mr. Brown is clearly a positivist, as far as worked flints are concerned, and one is tempted to speculate on his direct descent from Palæolithic ancestors, for, as if by some hereditary instinct, he is enabled to be quite positive as to the uses to which sundry implements have been put, to an extent, indeed, to which probably few of even that highly imaginative class of men, antiquaries, will follow him. Some examples of this positivism may be noticed. Thus certain flakes were "evidently intended for spear-heads" (p. 58); and certain "triangular stones . . . could hardly have been intended for use in any other way" than as arrow-heads, "they were no doubt hafted" (p. 117); but from the figures given of some of these stones one would be inclined to regard them as little else than castaways (Nos. 167, 169). In another case, "as the greater part of one side is flat . . . it is evidently done for the purpose of being held in the hand" (p. 86). Again, "the object of making such an instrument is clear," namely, "for insertion in a club" (pp. 94, 95). "There can be no doubt that . . . they have been, or were intended to be, inserted into sockets" (p. 109). No. 159, in which "we have a shaft-smoother, borer and knife included in one object" (p. 116), must have been the delight of some Palæolithic schoolboy! Where statements of opinion occur in such form as "*I* have no doubt," they are of course justifiable; but in this sceptical age it is risky to say "there can be no doubt." It is quite refreshing to hear that there are implements whose "use is almost beyond conjecture" (p. 98). Most likely differentiation in the use of tools did not go far in Palæolithic times.

In the illustrations it would seem that in some cases justice has hardly been done to the specimens, or we should not be told by so experienced a person as the author that No. 144 (Plate ii.) is "the finest example of Palæolithic work" that he has seen. There is, too, a deficiency that should be supplied in another edition: a map and a general section of the district would much help most readers; and these could well be given instead of some of the foreign objects, such as the eternal carved reindeer, &c., without which no anthropological work seems to be thought complete, and which, by frequent repetition, have grown to be nearly as irritating as the faces and figures ever obtruding themselves from the advertising columns of newspapers and magazines.

The frontispiece, by Mr. Worthington Smith, should be acceptable to the advocates of women's rights. The woman is represented as the skilled artist, whilst the man is the mere labourer!

OUR BOOK SHELF

Hand-book of Practical Botany for the Botanical Laboratory and Private Student. By Prof. E. Strasburger. Edited from the German by W. Hillhouse, M.A., F.L.S. (Swan Sonnenschein, Lowrey, and Co., 1887.)

PROF. STRASBURGER'S well-known work, "Das botanische Practicum," has already been reviewed in the pages of NATURE (vol. xxx. p. 214), so that a short notice may suffice for the present hand-book, which is essentially a translation of the *smaller* German edition. Only the account of the fall of the leaf (pp. 156–59) has been taken from the larger work.

The present edition has been fully revised by the author, and also contains a considerable number of editorial notes and additions. The latter are usually indicated by being inclosed in brackets. It would, perhaps, have been better if this had been done throughout, especially in the introduction. A number of additional figures have been inserted by the editor. These are almost all reproductions of familiar text-book illustrations. Many of them certainly come in well, but we cannot help feeling that the constant reappearance of old figures has become rather wearisome, and that in this instance it tends to take off from the freshness which was so pleasant a characteristic of Prof. Strasburger's "Practicum."

We much regret that no account of any of the seaweeds finds a place in this edition. The admirable description of Fucus in the larger treatise of the author might well have been introduced here, while we think that the editor would have been well advised to add an example of the red seaweeds on his own account, or at least to reproduce Prof. Strasburger's description of the fresh-water Batrachospermum. It is easy to see why the author, writing for German elementary students, omitted all reference to seaweeds in his smaller edition. In England we are in a very different position, and it is a pity that students should not at once be made acquainted with plants which are so instructive and so easily accessible.

As the editor explains in his preface that the translation was executed at a time of serious pressure, it would be unfair to enter into any detailed criticism. It must, however, be admitted that the signs of haste are very frequent, and that there is much need for revision in a future edition. There are one or two instances of this which cannot be quite passed over. At p. 11, "durchschnittlich," which means *on the average*, is translated "sectionally," while at p. 49 we have "carefully," where the author says "with advantage" ("mit Vortheil"). At p. 169, note 2, "perfection" should be "development," while on p. 208 the statement that "we *know* the angular outline of the crystals [in Spirogyra] even without reagents," has an odd effect. The word should of course be *recognise*. At p. 67 the use of the word "pits" for the deep depressions ("Grübchen") which lead down to the stomata in Aloe, &c., seems to us likely to confuse the beginner. The phrase "starch-builders" (p. 43, &c.) strikes us as awkward, and is certainly not accurate as a translation. The use of the term *laticiferous cells*, in speaking of Chelidonium, is unfortunate. The organs in question of course come under the head of laticiferous *vessels*.

In conclusion we may express a doubt whether the un-English form "fibro-vasal" has any advantages over the familiar word "fibro-vascular."

The appendices have been much expanded from the original indices of the author, and should be of great use to the student, to whom the book as a whole will be extremely welcome.

D. H. S.

Elementary Practical Biology—Vegetable. By Thomas W. Shore, M.D., B.Sc. (London: Churchill, 1887.)

THIS book is welcome more as a sign of the ever-growing attention paid to plant-structure than for any peculiar merit it has as a guide to the subject. The author fairly expresses his indebtedness to such practical books as Bower and Vines's, and claims originality only for his arrangement and treatment of the subject. The arrangement is as follows:—First comes an introduction dealing with the necessary apparatus and the preparation, &c., of objects. This is very concisely and sensibly done. Part I. deals with general vegetable morphology, treating in due sequence of the cell, the tissues, the systems of tissues, the apices of stems and roots, and cell-multiplication or cell-reproduction. Part II. is devoted to the Cryptogamia, beginning with the Fungi and working up to the vascular forms. Part III. is confined to the Gymnosperms, and Part IV. to the Angiosperms. So much for the arrangement. There may be no guide to practical work covering precisely all these types in this way, but text-books are by no means wanting which contain this arrangement of matter. The originality here is therefore not at all striking—perhaps fortunately so. As for the treatment, the student is conducted through the course with a baldness in the directions to note this and observe that, which reminds one of the style of a personal conductor through an historic building. The book has a purely practical aim, with the excellent purpose of preventing "cram"; but a student who should undergo this course of instruction, noting and observing no more than he is here directed to do, would find himself, at the end of it, the dispirited possessor of a mass of information which would result in a sad fit of mental indigestion. A practical guide of this kind throws too much of the burden of instruction upon the lecturer whose course accompanies it. The style of the whole book leads one to doubt the author's claims as a botanist to write it, and though it it may be a suitable guide to those who have to acquire a knowledge of botany in the course of their studies, it is practically useless for the rearing of botanists. Though one is reluctant to attribute a wrongly-spelt word to other than the conveniently necessary printer, the occurrence of Felicineæ, not once, but regularly, and, moreover, in the boldest and most conspicuous type of the headings of sections, does tempt one to think that the printer's fault lay in not having corrected it. A detailed criticism of the book would exhibit the author's imperfect acquaintance with the types discussed and his errors in description. Such, however, is beyond the scope of this notice.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.*]

A Plant which destroys the Taste of Sweetness

DURING his tenure of office as Governor of Madras, Sir Mountstuart Grant Duff found time, in a way at which I never ceased to marvel, to correspond with this establishment about every kind of detail connected with the botanical productions of Southern India. In one of the last letters which I received from him at the close of last year, before his departure from India, he writes:—"I send you inclosed in this a portion of that delightful plant *Gymnema sylvestre*, an Asclepiad. I shall be curious to know whether when it gets to you it retains the very interesting property that, if you chew carefully two or three leaves of it, it absolutely abolishes for the time the power of tasting sugar. This is no fable, for three of us, I being one, tried it this morning at breakfast with the most complete success. I ate pounded sugar after it without the faintest perception of its saccharine character. I also drank coffee without any sugar in it, and tasted it just as well as I ever did.

"General Elles has just been up to my room to tell me that he also found it abolish the power of enjoying a cigar. Do try it, and report to me, when we meet, whether it stands the long journey. This Gymnema might conceivably be important medically."

We found that the leaves sent by Sir Mountstuart Grant Duff did retain the property he described in a marked way. I immediately wrote to Mr. Lawson, the Director of Public Gardens and Plantations, Ootacamund, to endeavour to procure some seed which we might grow at Kew, so as to obtain material for future experiment. In a letter received from him this morning he promises to do this when the fruit is ripe. He has, in the meantime, been so good as to inclose in his letter a paper by Mr. Hooper, the Government Quinologist, which appears to me to well deserve the wider publicity of the pages of NATURE.

The whole matter is a good illustration of the useful work which can be done by scientific men in distant parts of the Empire, which indeed could hardly be done in any other way.

W. T. THISELTON DYER

Royal Gardens, Kew, April 11

[Mr. Hooper's paper will be found on pp. 565–67.]

Units of Weight, Mass, and Force

IT is not easy to follow Mr. Greenhill in his letter which appeared in NATURE of March 24 under the above heading. His main contention appears to be that "weight" connotes not "force" but "mass" in engineering formulæ. Surely it would be more correct to say that the primary idea among engineers is that of force, mass being of secondary consideration and being measured by means of force: the force most commonly referred to being that of gravitation, which is *the* force, *par excellence*, with which the engineer has to deal. And, I think it would be impossible to find any ordinary engineering formula involving W (which is generally supposed to stand for *weight*) in which W does not mean gravitation force. Also, in formulæ which have nothing to do with gravitation, and in which M (or *mass*) would naturally appear, the engineer puts $W + g$ instead of M, so as to enable him to express it in terms of his unit of force, the weight of a pound. Thus, the kinetic energy of a moving body is $\frac{1}{2}Mv^2$ (where M is its mass and v its velocity), and is quite independent of its position in space. Engineers, however, who only care about bodies near the earth's surface, express the energy in terms of the merely local phenomenon, the weight or gravitation force acting on the body, which is sufficiently constant for their purposes, and write $\frac{1}{2}Wv^2 \div g$. There is consequently a struggle between engineers and physicists as to whether "*pound*," "*ton*," &c., shall connote the fundamental engineering quantity, namely, *weight*, or the fundamental physical quantity, namely, *mass*; and, naturally, neither side is very willing to give way. The easiest way perhaps would be for the physicists to give another name to the mass-unit, and leave engineers to the enjoyment of their use of the word "pound"; though meanwhile the word might very well connote either *mass* or *weight* (*i.e.* gravitation force) according to the context, the terms pound-mass and pound-weight being used when special clearness is desired. But do not let us, as Mr. Greenhill seems to desire, use weight and mass as synonyms, so losing the advantage of a good word for no good reason.

But Mr. Greenhill's most incomprehensible attack is on the formula $W = Mg$.

The equation means fundamentally neither more nor less than that the force of gravitation on any mass near the earth's surface gives, or tends to give, to that mass a constant acceleration called "g," and is to be measured by mass and acceleration conjointly, in accordance with Newton's second law, the fundamental law connecting force and motion. The symbol = means "equivalent to," as it often does.

From this fundamental equation can be deduced special *numerical* equations by means of definitions of arbitrary standards. Thus a "poundal" is the force which will produce in a pound-mass an acceleration of a foot-per-second per second;

$$\begin{aligned} \therefore\ W(\text{in poundals}) &= M(\text{in pounds}) \times g(\text{in ft.-per-sec. per sec.}) \\ &= M(\text{in pounds}) \times 32,\ \text{approximately}, \end{aligned}$$

this equation being merely a *numerical* equation deduced from the fundamental physical equation above. For W (in poundals) means the ratio of the weight of a body to the force called a poundal, or weight per poundal, or $\dfrac{\text{weight}}{\text{one poundal}}$, and so is a mere number depending on the particular mode of measuring W: and similarly with the other quantities.

Again, a pound-weight is the force which produces in a pound-mass the acceleration g;

$$\therefore\ W(\text{in pound-weights}) = M(\text{in pound-masses}),$$

or *ambiguously*

$$W(\text{in pounds}) = M(\text{in pounds}),$$

which is another merely numerical equation, and of course also only an approximate one; as Mr. Greenhill incidentally shows by means of his hypothetical balance at the coal-pit.

Too much importance can hardly be laid on the radical distinction between a physical equation and the various numerical equations which by choice of special units can be deduced from it. This must be my excuse for dwelling so much on the above example. It throws light on the way in which the error cited by Mr. Greenhill in his last paragraph can creep in. Thus, if the mass of a body of weight W is $W \div g$, it really follows that the mass of a body whose weight is W pounds (*or*, less ambiguously, W pounds-weight) = W pounds-weight $+ g$; but by definition one pound-weight $\div g$ = one pound-mass, $\therefore$ the mass = W pound-masses. In Mr. Greenhill's example W is a mere number, and he shows the error caused by trying to insert it in a formula where W means a weight.

In conclusion, if Mr. Greenhill insists on the abolition of the equation $W = Mg$, will he kindly say how he would symbolise the connexion between the force of gravitation on a freely falling body and the induced acceleration g?

ALFRED LODGE

Cooper's Hill, March 30

The Association's "Geometry"

As the President of the Association for the Improvement of Geometrical Teaching did me the high honour to mention with special approval my work on geometry in his remarks before the

Association, printed in the twelfth Annual Report, 1886, I feel impelled, on at length receiving to-day, at this frontier outpost of scientific civilisation, a copy, long ordered, of the Association's "Plane Geometry," Part 2, to say a few words suggested by it, favouring accord in these fundamental matters.

The very first definition and first theorem show the glaring need in English for a word which the Germans have in *Strecke*. Such a word, meaning a piece of a straight line, is needed in the first definition, the definition of a circle, for all straight lines are infinite in size, and radii are pieces of straight lines, and not whole straight lines. This is unconsciously recognised, even in the first theorem, where for "piece of a straight line" the undefined word *distance* is used, inappropriate because of its association with ideas of measurement by a unit and length, and because of its different and confusing use in the phrase "shortest distance."

In the demonstration of this first theorem, "straight line" is used in its proper sense, though just before, in the first definition, it was bunglingly used in the sense here given to *distance*. For the part of a straight line between two definite points I have long used the word "sect," which, carried over to the sphere with the meaning part of the spherical line less than half, gives the key to two-dimensional spherics.

And this suggests another objection to the same first definition. It says a circle is a plane figure. Now one cannot even think of spherics without seeing how immeasurably better it is to define a circle as a curve It will be so defined as soon as the student reaches analytics, so why have him learn something only to unlearn?

In the fourth definition we have an over-used word, "conjugate" Two arcs which together make a circle should be called *explemental*. Explement is a natural third to complement and supplement. Again *converse* is a term of logic, and does not mean what it is here used to mean, that is, *inverse*.

In the introductory remarks to the fourth book I think it is a mistake to call hunger, love, courage, talent, wisdom, *magnitudes*.

A magnitude is whatever can be added to itself, so as to double. The very first sentence says: "In this book the subjects of the propositions . . are magnitudes in general;" but the whole treatment is founded upon *multiples*, and is only applicable where multiples can be made. Not only must we have an exact criterion of equality, we must be able to add without shrinkage.

A little farther on we meet the absurd statement, "Fundamentally, number is *counting*."

Now we know that counting is establishing a one-to-one correspondence between the individuals of an aggregate and of a standard group which was primarily the fingers. But a number is fundamentally a picture of an aggregate which for all counting purposes is as good as the aggregate itself—a picture consisting of a mark for each distinct individual in the aggregate, as III; and then secondarily a symbol for that picture, as 3

It is questionable whether Book IV Part 1, has any valid excuse for existing. Proportion for commensurable magnitudes neither calls for nor warrants treatment by multiples Sandeman, in the preface to his "Pelicotetics," speaks of "the phenomenon of incommensurability, through which alone arises any need of ratio, either the thing or the name." Euclid's marvellously elegant treatment of proportion is only admirable because of the difficulty it so deftly overcomes. To use it on commensurables is to use a Gatling gun on a plucked chicken. The illustration given under Definition 4 of this Part 1 (which definition needs the word commensurable inserted in it), "4 half-crowns = 5 florins," reminds one how badly England needs a decimal system of coinage, weights, and measures. No light is thrown on the compounding of ratios, but the error of A. J. Ellis is avoided He says: "The ratio of B to A means the order in which the multiples of B are distributed among those of A."

These are points suggested in first turning the leaves of a new book of most gratifying soundness May it ward off from England the misfortune America now suffers, in that our most popular book on geometry makes the fundamental blunder of basing the treatment of parallels on direction, uses in its proofs the stultifying formula, "a straight line is the shortest distance between two points," and from one end to the other makes us wish for an American Association for the Improvement of Geometrical Teaching. GEORGE BRUCE HALSTED

University of Texas, Austin, Texas, March 3

The Svastika as both Sun and Fire Symbol

THE late Prof. Dr. Worsaae ("Industrial Arts of Old Denmark") claims the ring-cross , as he terms it, as a sun symbol, and a small cup-shaped hollow for the moon; both these he places as belonging to the *later* Stone Age of Scandinavia, and, apparently, the only recognised emblems of that period. He observes, in one place: "How many hundred years, or, indeed, how many thousand years, before the Christian era the earlier Stone Age began, it is impossible to say."

The same writer places amongst the emblems of the *later* Bronze Age the wheel-cross  (the chariot wheel of the sun?). To this day, both in Denmark, Holland, and in parts of Germany, a wheel is frequently placed on the roof of a stable or other building, which is thus deemed protected from fire, especially if a stork can be induced to make its nest upon the wheel. The stork, owing to his red legs, was not inaptly considered an emblem of fire; he was also the herald of summer—he brought light and warmth. The Moqui symbol for the sun (as described by Dr. Dryer in NATURE, Feb. 10, p. 345) exists also on articles classed by Prof Worsaae as belonging to the later Bronze Age in Scandinavia, with the exception of the three marks of which he speaks, as indicating the eyes and mouth of a face.

According to Hyde ("Persian Religion," p. 38), "Idolaters as well as sun-worshippers existed in ancient Persia, and the worship of fire and that of idols were combined at one period."

Quintus Curtius, when describing the march of the army of Darius (writing, however, long after date), says:—"Darius was accompanied by an image of the *sun*, placed in a crystal, and the sacred *fire* carried on a silver altar."

The sun, which was regarded as a wheel, a store of gold, an eagle, was also styled the eye of Varuna.[1] The worship of Mithra was likewise a worship of the sun; Mithra was the god of daylight. He and Varuna were fabled to journey at even in a brazen car. From this has probably arisen the horse-sun and the wheel-sun. Euripides gives the sun a winged car; and, on coins from Eleusis, Dêmêtêr is represented riding in such a car drawn by two serpents.

The *svastika*  has been very generally allowed to be a symbol of Thor, who, to the Scandinavians, was the god of thunder and lightning and of the domestic hearth, and therefore of fire also. The arrows in the hand of Jove, the thunderer of Roman mythology, resemble somewhat a compressed or crushed *svastika*. The above form of this symbol, with a very slight variation 
, may be seen on a slab taken out of a Christian catacomb in Naples, and now in the National Museum there. A very natural inference is, that this stone sealed the grave of one who had suffered martyrdom by fire.

The *svastika* has been held to be an emblem of fire, as being the way in which that element was first produced by primitive peoples—a method which is said to be in use in certain Hindú temples at the present day. It consists in two crooked sticks being laid one across the other, and a hole drilled through both; a pointed stick being there inserted, this is rapidly twirled by the hands until the five points of contact become ignited.

---

[1] To the Persians, Varuna was the god of the clouds and of the celestial sea When this branch of the Aryans reached Southern India, he there became to them the god of the earthly sea. To the Greeks he was Ouranos; and to the Germans and Anglo-Saxons, the eye of Woden.

The ground-plan of some well-known Hindú temples in India is that of the Greek cross. The lightning, another of the attributes of Thor, the thunderer, from its zigzag course, may not unnaturally have been likened to a serpent. A Hermes, or torso, in the Museum at Arles, and labelled "A Statue of Mithra," shows that the serpent had its place in the celestial mythology of the ancients. This figure is entwined in the folds of a huge serpent, and between these are sculptured the signs of the zodiac.

During the Bronze Age, which, as regards Scandinavia, Dr. Worsaae fixes at from about 500 B.C. to 100 A.D., the form of the *swastika* received several modifications: amongst others, it became what he styled the single , or the double  thus, and also the three-armed figure , or triskele. In another place he says (*ibid.*): "Curiously enough, in the new Runic alphabet which was adopted at this time (later Iron Age or Viking period), the letter S, which recalls one of the old sun symbols, was called Sol or Sun."

The connection of the triskele with the serpent may possibly seem to some far-fetched, but a tolerably certain proof that it is not so is shown in a bronze brooch found, a few years ago, when excavating the Roman camp on the Saalberg, near Frankfort-on-the-Maine. This ornament is now in the local Museum of Homburg-v.-d.-Hohe. Inclosed in a ring of bronze is a triskele; each arm has a distinct serpent's head; they all turn the same way, as, it may be observed, do the arms of the *swastika* (or Crux Gammata). The connection of this symbol with the serpent survived even down to the so called "cinque-cento" period. It survived in Christian times—under the name of the *fylfot*—even down to the fourteenth or fifteenth centuries, and is alluded to by Sir J. Gardner Wilkinson ("Dalmatia and Montenegro," vol. i. p. 23). He speaks of finding this emblem, in the form of two snakes  entwined, "as a device upon some tombs in those provinces"; and adds:—"This symbol was used in early Christian times in England and other countries, among ornamental devices, in manuscripts, on tombs, and on church ornaments and vestments, from about 1011 to 1400 A.D., after which it is not met with in England. It is very common on monumental crosses of the fourteenth century, and was a favourite ornament of the Greek Church, whence it probably came into England and Western Europe: it is known in heraldry as the fylfot."

In the treasury of the Cathedral at Valencia, in Spain, there are two richly embroidered altar frontals, which (as stated by the officials in charge) formerly belonged to the church of old St. Paul's, in London, having been sold into Spain by our King Henry VIII. The needlework is a triumph of art. On each of these frontals is represented a portion of the old church. On one of them—which depicts our Blessed Lord going to crucifixion—a soldier of the Roman army, or of one of their allies, is represented holding a pennant on which is a *swastika* of the fylfot type.

In this brief sketch I have endeavoured to show the relations between sun- and fire-worship, both of which may have existed contemporaneously amongst primitive peoples, since light and warmth were naturally highly prized by them.

The Greek cross, or cross of Savoy (the centre of the ring-cross of the later Stone Age), appears to be the earliest known form of that symbol. A form of *swastika* of the Bronze Age—the triskele—may still be traced in the trinacria of the arms of Sicily and the Manx-man of our isles.

Did space permit, much more could be said regarding the *swastika* as a pre-Christian and a Christian cross.

Great Brampton, Hereford

HARRIET G. M. MURRAY-AYNSLEY

Important Points in the History of Earthquake Investigation in Japan

As the various instruments for recording earthquakes which have been invented in Japan appear destined to play an important part in future seismometrical investigations, and as the authorship of many of these instruments has recently formed the subject of a discussion, in which, although my name has been freely used, my distance from Europe practically prevents me from taking part, and which, so far as I can see, can only result in confusing those who are unacquainted with the work done in Japan, I venture to give the following notes as an outline of the more important points in the history of seismometry in this country.

In 1872, Dr. Verbeck, of Tokio, obtained approximate measurements of the range and direction of earthquake motion by means of an instrument consisting of a heavy slab resting on balls, the slab being the steady-point (Trans. Seis. Soc. vol. i. p. 23). The resemblance of this instrument to the lighthouse tables the invention of the late Mr. Stevenson is apparent.

In 1879, results which were probably more accurate than those of Dr. Verbeck were published in the Transactions of the Seismological Society (vol. i. p. 91), and the residents in Japan were astonished to learn that the amplitude of what were apparently severe earthquakes were to be measured in millimetres and fractions of millimetres rather than in inches. The results were obtained partly by Dr. Wagener and partly by myself. I worked with pendulums writing their records by what I still find to be the most delicate kind of pointers upon the surface of smoked glass. Dr. Wagener used a pendulum which was practically "dead-beat," and a pointer which gave a multiplied representation of the earth's movement. This was the first time that the necessity of multiplying-levers was recognised.

Shortly after this I published examples of diagrams of earthquake motion obtained by allowing smoked glass plates, at the time of a disturbance, to move for a period of three or four seconds beneath the pointers of a pendulum. The diagrams were short, but the results obtained respecting period, amplitude, and quantities calculable from these data, have not been shown by subsequent investigations to have been unsatisfactory (Trans. Seis. Soc. vol. i. p. 91, &c.).

About this time Prof. Chaplin and Mr. T. Gray independently constructed bracket seismographs (Trans. Seis. Soc. vol. i. p. 25). Mr. Gray's bracket seismographs were never specially described, but they still exist in the Imperial College of Engineering. Mr. Gray's next invention was a torsion pendulum seismograph, which, being suspended from horizontal levers which in turn were held up by horizontally placed springs, also recorded vertical motion. A curious feature in this instrument was that the horizontal levers were so supported that for slight displacements they had a constant leverage. In the same paper describing this instrument, Mr. Gray emphasises the importance of having seismographs so constructed that the steady-point should be in neutral equilibrium (Trans. Seis. Soc. vol. i. p. 48).

The next advance was made by Prof. Ewing, who, by using a bracket seismograph with a pivoted weight and a multiplying-lever writing on a continuously moving plate, obtained diagrams which inasmuch as they extended over a considerable portion of time were superior to all that had preceded them.

This instrument was described in Europe and Japan without the briefest mention of the fact that bracket seismographs, multiplying-levers, smoked glass plates, continuous records, &c., had a previous existence. Two of such publications are before me (Trans. Asiatic Soc. of Japan, vol. ix. p. 40, and Trans. Seis. Soc. vol. ii. p. 45).

At the time this excited no *public* comment, and it was not until Prof. Ewing distinctly claimed at least a joint authorship, not only of all bracket seismographs, but of all instruments which might involve the same principle, like the various forms of rolling spheres, rolling cylinders, conical pendulums, double brackets, &c., the inventions of Mr. Gray, that discussions arose. For one of these discussions see Trans. Seis. Soc. vol. iii. p. 9.)

Although Mr. Gray distinctly stated that he had experimented with bracket seismographs prior to the one introduced by Prof. Ewing (Trans. Seis. Soc. vol. iii. p. 5), and although I personally acquainted Prof. Ewing with this fact, so far as I am aware Prof. Ewing has never in any manner whatever referred to this. Mr. Gray's seismograph for registering vertical motion, which in its principle was a new departure in seismometric methods, was constructed and described in April 1881 (Trans. Seis. Soc. vol. iii. p. 137).

At the following meeting of the Seismological Society, Prof. Ewing described an instrument of a similar nature, and only differing from the one described by Mr. Gray in the details of an arrangement for compensating the variable leverage, an arrangement practically adopted by Mr. Gray in the above-mentioned torsion pendulum. This seismograph is now distinctly claimed by Prof. Ewing as his own (NATURE, December 23, 1886, p. 172).

In June 1881, Mr. Gray suggested several methods by which a pendulum might be rendered astatic (Trans. Seis. Soc. vol. iii. p. 145). This was followed by Prof. Ewing's device to obtain the same result by an arrangement which was closely foreshadowed by Dr. Wagener, who endeavoured to compensate the movement of a pendulum by a heavy-headed recording index (Trans. Seis. Soc. vol. i. pp. 66 and 67).

In addition to the seismographs here referred to, there are many others that might be mentioned. Amongst them we find the parallel-motion instrument of Mr. West, which was immediately followed by parallel-motion instruments the invention of Prof. Ewing and Prof. Alexander (Trans. Seis. Soc. vol. iv. pp. 22 and 30).

The development of the parallel-motion instruments may be taken as illustrative of what has happened with regard to nearly all the other seismographs, which in great measure have been gradually developed from something which preceded them.

By improving the bracket seismograph, Prof. Ewing made a considerable advance in seismometry, for which the workers in this country undoubtedly accord him their hearty thanks; but while describing a beautifully constructed, but at the same time inconvenient and obsolete arrangement of seismographs (NATURE, vol. xxx. pp. 149 and 175, and vol. xxxiv. p. 343), it is hardly fair that his fellow-workers, especially Mr. Gray, the most prolific of earthquake inventors, should be passed by unnoticed, and have their work practically appropriated.

Tokio, February 10 JOHN MILNE

Supposed Suicide of the Cobra

THE following observations may be of interest as bearing on the reputed suicide of snakes.

Yesterday, while riding over a bare sandy plain I caught sight of a large black cobra moving leisurely along. Having no other weapon with me but a ·450 express rifle, I halted my camel and fired, at about 50 yards, just as it was disappearing down a rat-hole. The bullet passed through the middle of its body without severing the spine; the head was immediately withdrawn from the hole, and the snake began to writhe in agony, rearing its head, spreading its hood, and striking wildly in all directions. I was about to put it out of its agony by a second shot when it struck close to its own tail, and my orderly cried out that now it had bitten itself and would soon die.

Though I had clearly seen that it did not bite itself, I thought this a good opportunity of seeing whether there was any truth in the popular superstition, and if not whether I could obtain any light on the mode of its origin. The following is the result.

The snake repeatedly reared its head, and after holding it reared, struck wildly at some piece of grass or stick; twice again it struck at its own tail, and on each occasion the natives with me declared it had bitten itself. This, however, I can assert, it did not: on one occasion it stopped just short of the skin: on the other, being apparently unable to check itself, it swerved slightly and struck the ground close alongside. It appeared to me that the snake in its agony struck wildly at the first thing that caught its eye and irritated it; in three cases this was its own tail, but as soon as it realised what it was doing—so far from there being a deliberate attempt at suicide—it did all in its power to prevent a fatal result.

It is conceivable that, under similar circumstances, owing to loss of control over its own actions a snake might actually bite itself, and there would be what might pass for a well-authenticated case of suicide; but such a case, did it ever occur, would probably be due to an accident and not to deliberate intention. I have no doubt, however, that the popular superstition finds its support in cases like that described; for the natives with me, if questioned, would reply that the snake had certainly bitten itself three times, the other apparently aimless strikes at sticks or grass having escaped their notice.

A similar explanation of the reputed suicide of scorpions was given in NATURE some time ago, but not having the file with me I cannot give the reference. R. D. OLDHAM

Camp near Pokran, in the Indian Desert, March 4

THE RETIREMENT OF DR. TYNDALL

WE have had on more than one occasion during the last six months to refer with regret to Dr. Tyndall's impaired health brought about by overstrain. Our readers will have gathered from the daily papers during the present week that although much recruited by rest, Dr. Tyndall has yet sent in to the managers of the Royal Institution his resignation of the Chair of Natural Philosophy, which he has held since 1853, and that the resignation has been accepted.

The managers and members, cordially appreciating Prof. Tyndall's services, and being anxious to mark their sense of the benefits he has conferred on the Institution during his long connexion with it, have done what was still open to them in the way of honourable recognition and regard. He has been nominated for election as Honorary Professor, a title previously borne by Sir Humphry Davy and Prof. Brande; and one of the annual courses of lectures will be called "the Tyndall Lectures." He has also been requested to sit for his bust, to be placed in the Institution, in memory of his relations with it.

At the monthly meeting held last week the following letter was read:—

Hind Head, April 3, 1887

DEAR SIR FREDERICK BRAMWELL,—I have halted in my reply to your letter of March 23, through sheer inability to express the feeling which the action of the managers, at their meeting on the 21st, has called into life.

And my reply must now be brief, for I hardly dare trust myself to dwell upon the "resolutions" which you have conveyed to me. Taken in connexion with the severance of my life from the Royal Institution, and with the flood of memories liberated by the occasion, this plenteous kindness, this bounty of friendship, this reward so much in excess of my merits, well-nigh unmans me.

And, let me add, the noble fullness of style and expression, which I owe to yourself, and in which the good will of the managers takes corporate form, is in perfect harmony with the spirit which it enshrines.

Of the managers existent when I joined the Institution, one only remains upon the present Board. The beneficent work of many of them is for ever ended; but I do not forget the sympathy and support which they extended to me during their lives. And now the long line of kindnesses culminates in words and deeds so considerate and appreciative—so representative of their origin in true gentlemanhood and warmth of heart—that they have almost succeeded in converting into happiness the sadness of my farewell.

With heartfelt prayers for the long-continued honour and prosperity of the Institution which I have served so long, and loved so well, believe me, dear Sir Frederick, most faithfully yours, JOHN TYNDALL

However much it may be regretted that Prof. Tyndall has felt himself compelled to withdraw from the onerous duties of a particular office, we may hope that, so far from this being a withdrawal from science itself, further leisure and rest may soon be followed by the old vigour, and that a fresh series of services may reward the labours of future years; for the work in which Profs. Huxley and Tyndall have been the best known among the pioneers is not yet half accomplished.

On this subject the *Times* writes as follows:—

"Dr. Tyndall's name, in conjunction with that of Mr. Huxley, stands for a symbol of the nationalisation of natural science as an educational instrument. Sir Humphry Davy and Michael Faraday, in the same position, flashed the light of science into minds already prepared by leisure and cultivation to receive it. Dr. Tyndall's professorship in Albemarle Street has synchronised, and by no casual coincidence, with the recognition of the claims of the masses to be scientifically instructed. Contracted as Sir John Lubbock complains the domain of natural science is still among educational appliances in general, it is extraordinarily large in proportion to the place permitted it when Dr. Tyndall commenced his courses a third of a century back. Scientific truth was valued and sought by the few then as now. They themselves scarcely regarded it as a subject which concerned the rest of the community. At large the most extraordinary obtuseness prevailed. The feeble attempts to impart a little superficial information in schools and lecture-halls rendered the darkness more visible. From the Royal Institution, as from the several centres occupied at various times by Mr. Huxley, poured a continuous expostulation against popular ignorance of the very bases of physical existence. The force of the appeals lay in their tone of moral anger at an apathy represented as a degrading baseness. Their special virtue was the determination, which never flagged, to abandon nothing of the exactness of science in popularising it. Prof. Tyndall, like his constant fellow-worker, has never for an instant looked upon the masses as entitled only to second-rate knowledge. They have had it of the highest and purest which it was within his means to supply. He has admitted no distinction between esoteric and exoteric teaching. He has not put off an audience even of children with the modern equivalents for the worsted orreries and Prince Rupert's drops of elementary philosophy fifty years ago. In his hands science for the most rudimentary educational purposes has been treated as reverentially as for the most transcendental. It has walked with head as erect in the Royal Institution theatre during the Christmas holidays as at a session of the Royal Society or the British Association. The result has been that, if the country has not learnt all it might and ought, it has learnt little which it will have to unlearn. It has not been condemned to drink either scientific dregs or scientific scum."

We regard the appearance of the article from which the above quotation has been taken as one of the results of the increased appreciation of science which has followed from the crusade in which Prof. Tyndall has played so important a part, and we confess it is not without misgivings that we contemplate a future, which we trust may be a distant one, in which Prof. Tyndall's unswerving advocacy of research for its own sake, and the example of his devotion to science, unsullied by considerations of filthy lucre, are no more among us.

We believe that all the arrangements at the Institution consequent upon Prof. Tyndall's retirement are not yet completed, but we learn that Lord Rayleigh has all but agreed to take some part, at all events, of the duties of the Chair.

This will be good news to all true friends of science. The Institution has a long and noble reputation to keep or to lose. In Lord Rayleigh's hands we know it will be safe.

PRIMROSES

THE very word awakens the pleasantest memories that remain to us from the time when we almost lived in the open air and enjoyed the intense delight of plucking wild flowers without let or hindrance; a pure and unalloyed delight actually experienced only in childhood, though it lives ever green in our hearts, and leavens the more serious pleasures of riper years. The primrose of primroses for all Britons is the wild yellow primrose that adorns woods, hedgerows, and banks from Cornwall and Sussex to the Shetlands, Orkneys, and Hebrides; for none is more lovely, though many among the endless variety spread over the north temperate and cold regions excel it in warmth and brilliancy of colouring. It is now about a year since botanists and gardeners met at South Kensington, whither they had brought their collections of living plants, comprising a large number of species and varieties of *Primula*, solely for the purpose of seeing and talking about primroses, polyanthuses, and auriculas; and the vast amount of information contained in the report of the proceedings of those assembled merits the attention of all naturalists, to say nothing of those who love flowers merely for the pleasure they afford the eye. Being hardy, primroses were among the first plants cultivated in this country when ornamental flower-gardening began, little more than three centuries ago. The old masters—Turner, Gerard, and Parkinson—introduce us to them, the first including in his "Libellus" only the *prymerose;* but at that date (1538) there seems to have been no such thing in England as the cultivation of flowers for their beauty alone. Gerard's first catalogue of plants cultivated in his garden at Holborn, and published in 1596, contains "primroses, birds eies, paigles, cowslips, and beares eares": respectively *Primula vulgaris*, *P. farinosa*, *P. veris*, and *P. auricula;* and this is the earliest English catalogue of professedly cultivated flowers. Parkinson describes in his "Paradisus" (1629) twenty-one sorts of "beares eares" or auriculas, and he mentions that the varieties cultivated were much more numerous than he intended describing. In the report alluded to, Shirley Hibberd states that in the year 1570 many artisans, driven from the Netherlands, settled in this country, bringing with them their favourite flowers, including the best of their auriculas. Thus it would appear that the auricula was one of the very earliest "florists' flowers" cultivated in this country; and it is hardly necessary to say that it is one of the chief favourites of the present day. One of the questions discussed at the Conference was the parentage of the true auriculas and the Alpine auriculas, a question upon which florists and botanists did not quite agree; and the only way of obtaining a solution of the problem is by experiment. It is nearly certain, however, that more than one species has been concerned in the production of the various cultivated races. On the one side it has been argued that the presence of true blue is almost absolute proof that they cannot all have descended from a species having yellow flowers; and it is true that both wild and cultivated plants which exhibit great variety in the colour of their flowers rarely offer both pure blue and pure red. The china-aster (*Callistephus chinensis*) is an exception, but whether both colours exist in the wild plant I cannot ascertain. Philip Miller, who was the first to cultivate it in this country, states that he received seeds from France of the red and white varieties in 1731 and of a blue in 1736. Amongst our native plants a very large number of those having normally blue or red flowers frequently produce white varieties; and I have myself picked red as well as white varieties of the bluebell (*Scilla nutans*), though it is true the red was not a very pure one. On the other hand, normally yellow flowers rarely sport into other colours.

To return to the primroses: the introduction in 1820 of the Chinese primrose added a permanently popular greenhouse flower, which is now raised by hundreds of thousands, indeed one might say millions, annually; and almost every florist of note has his special "strains" or varieties, varying in colour from pure white to crimson, and equally in the size and cutting of the leaves and flowers, which are either double or single. The double-flowered varieties are relatively difficult to cultivate, as they are propagated by offsets, and are less vigorous in constitution. Like the china-aster, this was unknown in a wild state until recently, when the Abbé David discovered it in the province of Hupeh.

Persons familiar only with the species of *Primula* hitherto mentioned can form no idea of the amount of variation exhibited by the whole genus, which embraces at least 110 distinct species, widely spread in the temperate and cold regions of the northern hemisphere, rare in warmer countries; and one is found in the extreme south of America. But some further particulars of their distribution may be interesting. The forms in Europe are numerous, and the number of species to which they may be referred varies from twenty to nearly forty, according to the views of different botanists. They are most numerous in the Alps, where they constitute one of the most charming features of the vegetation. In Asia, too, the genus is generally diffused, though by far the greatest concentration of species is in the mountains of Northern India, where upwards of fifty species occur, some of them ascending almost to the altitudinal limits of flowering plants. Quite recently Mr. Franchet has described a dozen new species from Eastern Tibet and the Chinese province of Yunnan; and Eastern China and Japan possess their peculiar species; one at least of the latter (*P. japonica*) being now common in English gardens. An isolated species, the gigantic *Primula imperialis*, inhabits the mountains of Java, and the genus is represented in South-Western Asia, in Arabia, even to the neighbourhood of Aden, by *P. verticillata*, the same species recurring in Abyssinia; yet none apparently is found in the mountains of Morocco. In America the distribution of the genus is peculiar, no species having been found in Eastern North America south of Canada, while in the western and central regions three or four endemic species inhabit New Mexico, Arizona, and California, though in the last-named country the genus does not extend south of the Yosemite Valley, where the charming *Primula suffrutescens* is at home. The latest discovery is a new species in the Santa Rita Mountains, near the Mexican boundary. Altogether, nine species are now known from North America, five of which, those in the Arctic regions, are also natives either of Europe or Asia, or both. But the most remarkable fact in the distribution of the genus *Primula* is the presence of a species in the extreme south of South America—a species so closely allied to the northern *P. farinosa*, which is common to Europe, Asia, and North America, that it has been alternately held as a variety of it and an independent species. When writing his "Flora Antarctica," Sir Joseph Hooker could find no character whereby to distinguish the South American primrose as an independent species; but in his recent "Flora of British India" he states that it differs in having large granulate seeds. On the other hand, Dr. Asa Gray ("Synoptical Flora of North America") treats it as the same as *P. farinosa*; yet it is probable that he did not examine the South American plant, although he includes South America in the range of *P. farinosa*, therefore it can hardly be cited as an expression of opinion on the subject. The plant is common in Fuegia and the Falkland Islands. Even admitting that it is sufficiently distinct to be admitted as a species, the genetic connection with *P. farinosa* is so close that as a phenomenon in distribution the question is immaterial. The southern limit of *P. farinosa* in North America, so far as known, is Colorado; therefore there is a break of nearly 90° of latitude.

The greatest diversity is exhibited by the Asiatic species, alike in stature, foliage, and floral structure. In a comparatively restricted region of the Himalayas grow the moss-like species, scarcely an inch high, including the flower, such as *P. minutissima*, and the tall *P. sikkimensis*, with an umbel of twenty to thirty delicate yellow flowers on a scape 2 to 3 feet high. Between these extremes there are all sizes and several distinct types of foliage. The Javan species alluded to above is perhaps the largest of the genus, having whorl above whorl of golden flowers, though it is closely approached by the beautiful and many-coloured *P. japonica*.

The recent novelties from Tibet and Western China include some of the most distinct and peculiar forms of the genus, but none of them is in cultivation.

There are many other interesting things connected with primroses, but I have perhaps already covered too much space. I may add, however, that by far the richest collection of living species was contributed to the show by the Royal Gardens, Kew—a collection largely brought together by Mr. G. C. Churchill, part author of the well-known book on the Dolomite Mountains, and cultivated by Mr. Dewar. It contained about fifty species, besides many hybrids and seminal varieties.

The report from which some of the foregoing particulars were extracted forms a part of the seventh volume of the Journal of the Royal Horticultural Society.

W. BOTTING HEMSLEY

ON THE ESTABLISHMENT OF THE ROMAN DOMINION IN SOUTH-EAST BRITAIN

BEFORE entering upon the matter which I have stated as the subject of this paper, I think it will be well to premise three notes: (1) on the general authority for the accuracy of the history; (2) on the geography of the approaching coasts of Gaul and Britain; (3) on the pronunciation of names delivered to us in the spelling of the Greek language.

(1) The account of the invasions which I adopt is that of Dion Cassius. His history, in general, is orderly and full. He appears to have been a man of rank, and doubtless had command of State documents. He seems to have been well acquainted with every movement in the Courts of several successive Emperors. He has carefully explained why he was unable to continue his Roman history beyond the time of Severus with due accuracy. The time of the invasion of Britain was about 170 years before the composition of his history—an interval almost equal to the length of our Hanoverian dynasty; and his account of the wars in Britain may claim to be considered as trustworthy as our histories of the campaigns of Marlborough.

(2) In regard to the geography, it is to be observed that the coast-tract in the north of France, apparently from the mouth of the Seine to the mouth of the Scheldt, is called Γαλατία (Galatia). This name occurs at least twice, in separate books of Dion. By Ptolemy it is called Κελτογαλατία Βελγική.

(3) The English writers who have given any attention to this history have had, I believe, no knowledge of the pronunciation of the Greek words. Mitford, however, in his "History of Greece," had pointed out some of its peculiarities. The difficulty is now greatly removed by the publication, at Boston, U.S., of the "Grammar of Modern Greek," by E. A. Sophocles. I extract the substance of his notes which apply best to the present purpose:—

β is the English *v*, or sometimes *bh*.
δ is the English *hard th*, as in *that*, *those*.
θ is the English *soft th*, as in *thin*, *thorn*.
μπ is the English *b*.
νδ or ντ is the English *d*.
ι is the English *ee*, as in *seen*.
ου is the English *oo*, as in *soon*.

There is no reason to think that the pronunciation has changed for many centuries. In the Byzantine Greek histories of the Crusades, there are many opportunies of making comparisons of the Greek and the Latin names of places and persons, which appear to follow the same rules as at the present time.

Thus, the name given by Dion to the lady who commanded the Britons in their grand movement against the Romans is spelt by him Βουνδούικα. Interpreted by the list of equivalents just given, it becomes in English letters and sounds, Voo-doo-ee-ka; and this I believe to be the true rendering of the name. Still, I dare not depart from the established custom; and I shall therefore (unwillingly) adhere to the long-used English spelling, "Boadicea."

I now enter upon the national history.

In the reign of the Emperor Claudius (there is no farther indication of time) Kunobellin reigned at Camalodunum (undoubtedly the modern or Saxon Colchester, "the fortress on the River Colne": the Latinised original name is literally "Camal-hill" or "Camal-fort" (a name somewhat similar to this occurs in Arthurian legends). Kunobellin is mentioned by others as King of the Trinobantes. Dion remarks, "they (the people) were not self-governors, but lived under kings."

Vericus (Βέρικος), a political exile from Camal-dun, persuaded the Emperor Claudius to given him military assistance (apparently for restoration); and the Roman general Aulus Plautius was sent from Galatia, and (after a ridiculous mutiny of the soldiers) landed in England. Remarking that he had no motive for entering Kent, and that his object was to reach Camal-dun as soon as possible, I think it likely that he rounded the North Foreland, and debarked at Southend on the west side of Shoeburyness; where there is an excellent beach two or three miles long, sheltered from the open sea, for landing; and a good plain, for temporary encampment.

Without detailing all the affairs of Plautius with Kunobellin and Kunobellin's two independent sons, Kataraktos and Togodumnos, I shall only say that, after a very unsuccessful struggle with the Britons, apparently among the woods and marshes of the Crouch (a complicated river), Plautius retreated, in veritable flight, towards the west. He had, however, made peaceable terms with the Vothuni (a tribe not otherwise known, I believe); and, leaving a guard there, proceeded till he came to a river, deep but fordable, which he passed with some difficulty. This river, I have no doubt, was the Lea, the largest of the Essex rivers, and running in a valley which is in some parts marshy. In crossing this river, he was greatly assisted by the Κέλτοι, who were accustomed to cross rivers in their armour. (It seems not improbable that these Κέλτοι had been levied in the eastern parts of Galatia and the regions of the Scheldt.) The Roman army, by this real flight, reached the tract opposite London. We have now to consider the state of land and water before them

So far as we can judge, there had never been any power in the country which could have embanked any of the marshes as we see them now. The sea-water, scarcely salt (much fresh water having entered from the Thames and the smaller rivers) ran up with an insignificant tide, above Rotherhithe and to the borders of Southwark, in a great arm of the sea, never less than two miles wide. This gulf is called by Dion 'Ωκέανος. It was shallow, in some places actually bearing trees. (See Mr. Spurrell's "Early Sites and Embankments on the Margin of the Thames Estuary," *Archæological Journal*, vol. xlii.) To the point opposite London applies the sentence of Dion, "ἐπὶ τὸν Τάμεσσαν ποταμόν, καθ' ὃ ἔς τε τὸν 'Ωκέανον ἐκβάλλει." And this was Dion's mouth of the Thames, and here was the head of the gulf. There was a bridge at a small distance, which I conceive to have been near the site of William the Conqueror's bridge or modern London Bridge. It is remarkable that there is no mention of a town; but probably Southend was the real port of Britain, and the march of the Romans was on the harbour-road.

The sea-water, after the long passage up the shallow gulf, had almost lost its tidal character, and become a mere lake. The Kelts of the army forded the water, and the Romans crossed at the bridge. And now the army, much shattered, was in Kent or Surrey. The Emperor Claudius, on hearing the state of affairs, sailed in person with troops to Marseilles, crossed France to the north coast, and landed in Britain to join Plautius. There can be no doubt that he landed at one of the southern ports of Kent, as Winchelsea or Rye (the whole of Kent being evidently held in perfect quiet); and the question arises, Where was Plautius waiting? and where did Claudius join him?

It is possible that Plautius may have waited in the neighbourhood of London Bridge; but I offer a conjecture which I think more probable. In the grounds of Holwood (near Farnborough) at the eastern corner of Hayes Common, at an easy day's march from London, and in the direct line from London to the south-eastern ports, are the extensive remains of the earthworks of a large fort, in the best style of Roman permanent encampments. In its straight lines of outline (where circumstances permit), its rounded angles, its lofty inner rampart and its lower second rampart, it admits of comparison with the most complete of those which Agricola established in his marches through the Scotch Highlands, and which are described in General Roy's "Military Antiquities." It is called, in the neighbourhood, Cæsar's Camp. The little river Ravensbourne (which ultimately joins the Thames at Deptford Creek) rises in a strong spring close to the entrance. I think it probable that Plautius wintered here, and was joined here by Claudius

The united armies marched at once for Camal-dun, and captured it. And it would seem probable that they immediately gave it its present form, and a fairer or nobler provincial and military capital (as adapted to ancient warfare), within my knowledge nowhere exists. It is planted on a steep parallelogrammic hill. The slope of the ground at the east gate was eased, within my recollection, in the year 1816. On the south side, a little less steep than the other sides, the ground has been heavily scarped, and faced with a stone wall. The whole town is surrounded by a stone wall at the brow of the slope, rounded at the angles; the little river Colne is on the north side, and there the wall is lower in the valley. The dells on the south and west sides converge to an angle, near which is placed the principal gate of the town. The great streets are in the true Roman form of capital T, and all the small streets are at right angles. The citadel, I suppose, was in the space on the north side of High Street, in which the castle (a Norman building) now stands.

It would appear that the Romans, as residing in a country which was likely to be troublesome, took early steps for making a great road across it; and then was made the great western road by Marks Tey, Coggeshall, Braintree, Dunmow, to Stortford, on the River Stort (which is the largest affluent of the Lea); and then was formed the large intrenched camp of Wallbury, about two miles south of Stortford, on the Essex side of the river.

And after this was made the road to London. The reason for my placing its date subsequent to that of the western road is singular, but certain. The road to London does not start independently from Colchester: the western road is used as far as Marks Tey, and there the London road branches off at an angle of about 40° (roughly estimated). I have personally surveyed this, taking views from the neighbouring grounds, and can assert that the road from Colchester to Coggeshall passes straight through Marks Tey, totally unaffected by the London road. The same thing is exhibited clearly on our Ordnance map.[1]

All appeared to be peaceably established. And now came the terrible outbreak.

Dion suddenly states that two cities were destroyed (their names or positions are not mentioned), and 80,000 of the Romans and their allies killed, and that this was done by a woman, to the great shame of the Romans; that this was foretold by divine inspiration (τὸ θεῖον); that there came from the Senate-house (βουλευτήριον), at night, barbarous noises, with laughter; from the theatre came a sound of tumult with lamentation, when nobody was near; some houses were seen under water in the Thames; the ocean between Britain and Galatia was disturbed, and had a bloody colour. The cause of the war was the exaction, by Claudius, of money raised by confiscation (δήμευσις), which Claudius gave to the principal men of the Britons

---

[1] The modern name Marks Tey is an error for Marks Tye, Tye being the customary word in Essex and Suffolk for a bifurcation of roads.

(if I have correctly translated the passage); and Decianus Kalus (the Superintendent of the island) asserted that these sums were to be treated as contributions (*ἀναπόμπιμα*) to be sent to Rome. To this was added that Seneca—who was not only philosopher, poet, and Minister of State, but also the greatest usurer in Rome—having lent (*δανείσας*) ten millions (*χιλιάδας μυριάδας*; which if in sestertii would amount to about 80,000*l.*) *ἄκουσιν* (I do not understand this word) on sound hopes of interest, suddenly, and with violence, exacted the return of the whole; that it was Boadicea (Voo-doo-ee-ka) who principally caused the rising of the Britons. In the usual history of this lady there is much to be corrected. She was *not* Queen of the Iceni, though of the royal family (*γένους τοῦ βασιλείου*). She had *no* husband or children. There is not the slightest allusion to *any* personal insult. She did *not* die in battle, but died from disease (*νόσῳ*) after the battle.

Boadicea, as Dion remarks, was greater than woman. She collected the army of about 120,000 men. She mounted a *βῆμα*, made in the Roman fashion, to raise her from the mud. She was tall in person, very awful in countenance, with keen eyes and a rough voice; her abundance of yellow hair fell far down her body; she had chain-armour of gold, a variegated vest, and a thick cloak.

A very long speech is given, of which the following are the principal heads:—The superiority of liberty to slavery; the criminal character of the taxes, some even levied from the dead; the Britons themselves are the cause of these evils, not having resisted them soon enough; the habits of our enemies expose them to far greater difficulties than those which we endure; and other remarks, finishing with a kind of enchantment over a hare.

The Britons proceeded to terrible and savage excesses, the worse because Plautius was absent, having gone to Μῶννᾳ; which, if it be the same as the *Μόνα* of Ptolemy, is the Isle of Anglesey. But this appears to me to be, etymologically, very doubtful; and, practically, I think it very improbable that, in such a state of affairs, Plautius would have gone, by a difficult march, to such a distance. Plautius however returned, and a battle soon took place.

There is no difficulty in fixing on the site of this, one of the great battles of history. In the neighbourhood of Linton, at the north boundary of Essex, in a space perhaps of two square miles, are places which still bear the names of Shudy Camps, Castle Camps, Camp's End, Camp's Green, Camp's Castle. Every one of these has undoubtedly been the scene of a desperate struggle. And, finally, there are the three mighty mounds, known as the Bartlow Tumps, which, as I understand, have been identified as containing Roman remains.

Dion has given a long account of the various phases of the battle. Boadicea died of illness (*νόσῳ*), and the Britons were driven off the field. The battle was sufficiently decisive to prevent the re-appearance of the Britons in force; but still it appears, I think, not to have made a complete conquest.

The news was welcomed at Rome with very great interest by the Emperor, the Senate, and every rank of society.

G. B. AIRY

THE EUROPEAN PREHISTORIC RACES

IT would be difficult to overrate the scientific value of the discovery of human remains made last summer in Belgium, and briefly noticed in NATURE of February 24 (p. 405). Hitherto serious doubts have prevailed regarding the true character of the Canstadt, Neanderthal, Eguisheim, Olmo, and four or five other skulls, which are collectively referred to the oldest known race in Europe, but which, owing to their apparently exaggerated simian features, have been looked on with suspicion by Pruner, Virchow, and others, as possibly exceptional or even mere pathological specimens. But these doubts have at last been set at rest by the lucky find made last June by MM. Max Lohest and Marcel de Puydt, who, during their explorations of a cave on the slope of a wooded hill on the banks of the Orneau, in the commune of Spy, province of Namur, came upon numerous remains of two individuals amid hitherto undisturbed Lower Quaternary deposits, and in association with the bones of *Rhinoceros tichorinus*, *Elephas primigenius*, *Ursus spelæus*, *Hyæna spelæa*, *Felis spelæa*, the horse, wolf, sheep, and other now extinct and surviving Pleistocene animals. These remains have been carefully examined by M. Julien Fraipont, Professor of Animal Palæontology in the University of Liége, who unhesitatingly refers them to the Palæolithic race, to which King's expression "*Homo neanderthalensis*" may now be confidently applied. Taken especially in combination with the peculiarities of other parts of the skeleton, such as the evidently angular position of femur and tibia, implying a non-erect or stooping attitude in standing or walking, the skulls of the two Spy men show clearly that those of the Canstadt and Neanderthal men are in no way aberrant, but perfectly normal specimens. They obviously represent a Palæolithic and pre-Glacial race, the earliest of which there is any distinct record, which was already spread over West Central Europe in early Quaternary times, and which De Quatrefages and Dr. Hamy now believe may ultimately be traced back to the later Tertiary epoch.

A far better idea of the physical characteristics of the *Homo neanderthalensis* can be had from the remains of the Spy men, than from any others hitherto brought to light. Prof. Fraipont, who devotes a lengthy memoir to the subject in the *Bulletin* of the Royal Belgian Academy for December, gives detailed osteological descriptions of the two more or less perfect skeletons, from which it appears that of one there are extant: the skull, relatively very complete; the right portion of the upper jaw, with five molars; a fragment of the left portion, with the two premolars, incisor and canine; the under jaw, nearly complete, with sixteen intact teeth *in situ*; a left clavicle; the right humerus, less the upper epiphysis; the left humerus, less both epiphyses; the left radius; the right femur, nearly complete; the left femur, complete; the left tibia, complete; the right heel. Several of the parts here missing are supplied by the second skeleton; and there are also numerous vertebræ, fragments of ribs, &c., which cannot with certainty be referred to one rather than the other.

The first skull (No. 1) includes: the frontal bone from the superciliary arches and naso-frontal suture to the parieto-frontal suture; the right parietal, nearly complete; the upper half of the left parietal; the occipital, less a considerable portion of the region of the cerebellum. Of the second skull (No. 2) there remain: the frontal, very nearly complete; the right and left parietals, complete all but a few fragments of the former: the right temporal, nearly complete; the left temporal, complete; the occipital, less a portion of the region of the cerebellum.

The first is very long, very depressed from above, and narrow, being decidedly platidolichocephalic, with cephalic index 70, as compared with 72 of the Neanderthal skull, and 67·65 of the Clichy. The second is subplatidolichocephalic, with apparent index 74·80, and general characters less pronounced than those of No. 1, but not to such a degree as to prevent the two from being referred to the same race. Of both, the longest antero-posterior diameter is about the same, 200 and 198 to 200 mm. respectively, the former corresponding exactly with the Neanderthal. But the transverse differs considerably, being 140 and 15[illegible], between which comes the Neanderthal with 144 mm. On the other hand, the antero-posterior frontal curve of the first coincides exactly with that of the Neanderthal, the frontal itself being, like it, low and retreating. Another typical feature of this frontal is the great development of the superciliary arches, although slightly less prominent than those of the Neanderthal and Eguisheim. The distance between their outer extremities is no less than 122 mm., while the arches converge at the very root of the nose, leaving a slightly depressed intervening glabellar region, this region differing perceptibly from that of the Neanderthal, in which the glabella is prominent.

Although otherwise well preserved, the under jaw of No. 1 unfortunately lacks the condyles, which would have enabled us to settle the important question of its relative prognathism. This jaw is very high and massive, and the well-preserved teeth of both present the general characters found amongst the New Caledonians and other modern races of low type. The canines and incisors of the under jaw are worn obliquely and outwardly, those of the upper jaw obliquely and inwardly, although in general to a less extent than amongst the Neolithic races.

The right femur of No. 1 is not large, but very strong and heavy, and is specially remarkable for its typical forward curvature. The great posterior development of the articular surface of its condyles, taken in connection with the general curvature of the body, shows that the Spy men walked with the knees bent forward, the thigh being obliquely curved forward and downward, and the leg reversed backwards. In other words, the femur was adjusted obliquely to the tibia, which was itself strong, thick and heavy, but very short.

The discoveries at Spy are specially valuable because found associated with other remains which enable us to determine approximately the epoch of analogous finds elsewhere. The already mentioned fauna, as well as the character of the coarse flints occurring in the same undisturbed strata, would seem to indicate that both the Spy men, and their Canstadt and Neanderthal congeners, must have flourished in the *époque Moustiérienne* of French writers, that is, during the early period of the mammoth, and long before the beginning of the Reindeer Age. They were consequently more recent than the race of the *époque Chelléenne*, which was contemporary with *Elephas antiquus*, but of which no actual remains, beyond the objects of its industry, have yet been discovered. That they belonged in any case to pre-Glacial times seems evident from the remarkable absence of the reindeer, which is not numerously met in West and Central Europe till the Ice period.

M. Fraipont's comparative study of these remains makes it thus abundantly evident that they belong to the Neanderthal type. The two skulls even serve as a sort of missing link between the Neanderthal and the others usually referred to the same race. This race, whose presence in Europe during the early Mammoth Age has now been clearly traced from Stængenæs in Scandinavia to Olmo in Italy, seems in a way to have been resuscitated by the fortunate discovery in the limestone cave on the banks of the Orneau. Their dry bones again assume flesh and blood, and science is enabled confidently to describe the men of Spy as a short, but far from "feeble folk," thick-set, robust, walking knees foremost, and with a figure somewhat analogous to that of the modern Lapps, who also still waddle and are nearly all more or less bandy-legged. Their broad shoulders supported a long, narrow, and depressed head (different therefore from that of the true Papuan, which is long, narrow, and high), with very prominent superciliary arches, enormous orbits, low and retreating brow, high and massive cheek-bones, receding chin. No modern race, however low in the scale of humanity, is collectively characterised by all these traits, so that it may be safely affirmed that the ethnical type of the men of the Mammoth Age has become practically extinct, either through further evolution within itself, or by extirpation, or more probably by fusion with men of a higher physical standard.

It is noteworthy that the points which most separate the men of Spy from the present inhabitants of the globe are precisely those which bring them into closer relation with the anthropoid apes in general, rather than with any particular species of anthropoids. These points, which may thus fairly be described as pithecoid or simian, are chiefly: the prominent superciliary arches, normal in the young male gorilla and adult female orang; the extremely low retreating frontal, constant in the chimpanzee of both sexes and all ages; the almost chinless receding lower jaw, highly typical of gorilla and chimpanzee; lastly, the peculiar curvature of the femur, combined with its adjustment to the tibia, suggesting in the vertical position an attitude somewhat analogous to that of chimpanzee and gorilla. On the other hand, all the other features of cranium, trunk, and limbs are distinctly human, while the cranial capacity alone would suffice to justify the claim of *Homo neanderthalensis* to membership with the human rather than with the simian family. However great the distance separating him even from the lowest of modern races, far greater, undoubtedly, is the interval between him and the highest of the modern anthropoids. At the same time this interval becomes perceptibly diminished by Gaudry's discovery of *Dryopithecus fontanii*, an anthropoid ape of the middle Miocene epoch certainly less simian, or rather more human, than any of its present congeners. Its lower jaw is perceptibly less receding than that either of the gorilla, orang, or chimpanzee. The interval tends to be still further reduced when we remember that, although the *Homo neanderthalensis* is the earliest human type of which any bodily remains have hitherto been discovered, there is a still more primitive race revealed to us by the rude palæolithic implements frequently occurring in association with *Elephas antiquus*, and in later Tertiary deposits considerably older than the Lower Quaternary of the Spy cave. Whenever any characteristic remains of this primæval race come to light, a distinct approach will have been made towards a solution of the difficult questions connected with the genetic descent of mankind.

A. H. KEANE

AN EXAMINATION OF THE LEAVES OF GYMNEMA SYLVESTRE[1]

GYMNEMA SYLVESTRE (R. Br.) is an asclepiadaceous plant growing in the Deccan peninsula, from Concan to Travancore; it is also met with in Assam, and on the Coromandel coast, and is distributed in the continent of Africa. It is a stout woody climber, with long slender branches.

The leaves are opposite, entire, from 1½ to 3 inches long, and from 1 to 2 inches broad, elliptic or obovate, acute or cuspidate, rarely cordate at the base, membranous, thinly pubescent on both sides, the upper surface of a darker green than the lower. *Gymnema sylvestre* is mentioned in the non-official list in the Pharmacopœia of India (1868), and in Dr. Dymock's "Materia Medica of Western India." The powdered root has for a long time been known among the Hindus as a remedy for snake-bites; in such cases it is applied locally to the part affected, and also taken internally in the form of a decoction. But the most curious circumstance connected with this plant was first noticed by Mr. Edgeworth, who discovered that by chewing some of the leaves it destroyed the power of the tongue to appreciate the taste of sugar; he found that powdered sugar, taken immediately after masticating some of the leaves, tasted like so much sand in his mouth, and this effect lasted for twenty-four hours. Dr. Dymock, reviewing this property, said he was unable entirely to confirm this statement; his experience was that sugar taken into the mouth after chewing the fresh plant had a saltish taste, but was still easily recognisable.

---

[1] A paper, read at a meeting of the Nilgiri Natural History Society Ootacamund, by David Hooper, F.C.S., March 7, 1887.

Some authentic leaves were procured by Mr. Lawson from Guindy Park, Madras, who placed them at my disposal for chemical examination. They had a bitterish astringent and slightly acid taste. After chewing one or two leaves it was proved undoubtedly that sugar had no taste immediately afterwards; the saltish taste experienced by others was due to an insufficiency of the leaf being used. Sugar in combination with other compounds in dietetic articles is plainly destroyed as to its taste after using these leaves. In ginger-bread, for instance, the pungency of the ginger is alone detected, the rest is tasteless meal; in a sweet orange the taste of the sugar is so suppressed and that of the citric acid consequently developed that in eating it resembles a lime in sourness. Among the several kinds of foods, drugs, and beverages which affect the palate Gymnema does not pretend to render them all tasteless; it does not affect pungent and saline things, astringents, and acids. It is limited to apparently two diverse substances, sweets and bitters It has been noted that sugar taken after the leaf tastes like sand, so I have found that sulphate of quinine taken after a good dose of the leaf tastes like so much chalk. I am not going to propose its use in the administration of nauseous drugs, until the medical properties of the Gymnema have been more studied, otherwise the quantity of the vehicle taken may prove to counteract the effect of the medicines. The experience of several friends as well as my own is that the effect does not last for twenty-four hours as stated, but for only one or two hours; after that time the tongue resumes its appreciation of all that is sweet or bitter.

The powdered leaves were submitted to the action of various solvents, and by this means it was ascertained that the peculiar property of Gymnema leaves was dissolved out by alcohol, and, as it occurred in the aqueous extract of the residue, it was therefore soluble in water. As benzene and ether took from the leaves certain principles of the same appearance and weight, it was conceived that nothing would be gained by using both solvents; the preliminary extraction was therefore made with ether rectified from water and spirit. The ether extract consisted of chlorophyll and two resins separated by their solubility in alcohol. The resin insoluble in spirit formed the larger portion; it was soluble in chloroform, bisulphide of carbon, and benzene. It was elastic and tenacious, decomposed by warming with nitric acid, the product being precipitated with water; only partially saponified with caustic potash. Sulphuric acid dissolved it in the cold, giving a green solution. It seemed to consist principally of a neutral resin. The resin soluble in spirit was readily saponified with soda, and gave a permanent bluish-green colour with sulphuric acid; like the former resin, it was of an acrid nature, and left a tingling sensation in the throat.

The alcoholic solution of the leaves was almost entirely soluble in water; in fact, by treating the leaves separately by alcohol and water, 36·37 per cent. organic matter was extracted; by treating the drug with water alone 36 per cent was removed. By direct experiment it was found that in the former extract 0·47 per cent. was an acrid resin similar to those found in the ether extract. The aqueous solution of the substances soluble in alcohol had a decidedly acid reaction; it gave no coloration with ferric chloride, showing absence of tannin. It was deepened in colour with alkalies, but gave a bulky precipitate with sulphuric, nitric, hydrochloric, and acetic acid. It reduced Fehling's solution on boiling, and gave a cloudiness with Nessler, a precipitate with lead acetate, but none with tannin or picric acid. The precipitate caused by sulphuric acid was collected on a filter and washed till it ceased to give a cloudiness with barium chloride. It yielded a greenish powder, insoluble in water, but soluble in alcohol, ether, benzene, and chloroform. With potash, soda, and ammonia it afforded fine red solutions with orange-coloured froth, but they were both precipitated on the addition of the mineral acids. It dissolved in concentrated sulphuric and nitric acids with intense red colour, but in both mixtures it was destroyed and precipitated by water. It fused at about 60° C. into a blackish brittle mass. Heated in a test-tube it gave off fumes of creosote, but no crystals were obtained in a subliming apparatus. Gently ignited it burned with a bright flame, leaving no ash. It was thrown down as a bulky gray mass by acetate of lead; the lead salt decomposed by sulphuretted hydrogen in water left the substance in the reddish evaporated filtrate from the lead sulphide. The body just described has the characteristics of an organic acid related in some particulars to chrysophanic acid, but having some distinctly peculiar reactions, and possessing the anti-saccharine property ascribed to the leaves. I propose to call it *Gymnemic acid*.

Gymnemic acid forms more than 6 per cent. of the constituents of Gymnema leaves, in combination with a base which has not been isolated. Another organic acid was present in the lead acetate precipitate, which was identified as tartaric acid. The filtrate from the insoluble lead compounds was treated with sulphuretted hydrogen gas, and the clear liquor after evaporation was examined for sugar. Glucose was detected in some quantity by its immediate and abundant reduction of Fehling's solution; the sugar examined in a polariscope had a left-handed rotation.

Chloroform agitated with an alkaline solution of the leaf left a crystalline residue of a brownish colour; it had a bitter taste, and acted as a sialagogue. With the ordinary alkaloidal reagents it afforded coloured precipitates, but was a neutral principle. Its further examination together with that of gymnemic acid are reserved for further investigation.

The leaves after being exhausted with ether and then alcohol were treated with water. The gum was detected and estimated in the usual manner. A carbohydrate, optically inactive, and, after boiling with acid, reducing Fehling's solution, was found in this extract.

Diluted soda removed a brownish liquid which consisted of albuminous matters only partially soluble in alcoholic and acetic acid. These were not weighed but calculated by difference.

A solution of 1 per cent. hydrochloric acid was employed to remove the oxalate of calcium. A microscopical examination of the powdered leaves showed a fair sprinkling of the conglomerate crystals or raphides so well known to exist in rhubarb. The dilution of the acid menstruum rendered this process very tedious, so a stronger acid was used and the marc washed with it until ammonia produced no cloudiness. The collected liquors were allow to deposit, the sediment was then collected on a filter, dried and weighed; then incinerated and weighed again. The calcium carbonate was calculated into oxalate, and the difference between this and the first weighing was reckoned as pararabin. No oxalic acid was found in a free state.

The ash of *Gymnema sylvestre* is very high, a fact in accordance with the amount of lime salts it contains. Gentle ignition of the air-dried leaves left as much as 11·65 per cent., and about one-half of this was calcium carbonate. One hundred parts contained—

15·41 soluble in water.
78·71 soluble in acid.
5·88 sand and siliceous residue.

The cellulose was estimated by steeping the leaves in sulphuric acid of specific gravity 1·50 for 30 hours, washing, drying, burning, and deducting the ash; this result did not differ materially from the weight of the totally exhausted powder treated with chlorine water.

The following is a tabulated analysis of the powdered and sun-dried leaves :—

Ether extract (chlorophyll and resins) ...	5·51
Alcoholic extract (gymnemic acid, tartaric acid, glucose, neutral bitter principle, resin, &c.)	19·50
Aqueous extract (gum 1·45 per cent., glucose, carbohydrate, and extractive) ...	16·87
Alkaline extract, by difference (albuminous and colouring matters)	8·15
Acid solution { calcium oxalate	7·64
Acid solution { pararabin	2·74
Ash (balance of)	5·69
Cellulose	27·86
Moisture	6·04
	100·00

NOTES

THE Conference called by the French Government to consider the means to be adopted for the construction of a photographic chart of the heavens, meets at Paris on Saturday next. We believe that the Astronomer-Royal and Mr. Common have been delegated to represent the Royal and the Astronomical Societies.

THE Rev. S. J. Perry and Dr. Copeland have accepted Dr. Bredichin's invitation to observe the total solar eclipse in August next at his residence near Moscow.

WE regret to announce the death of Dr. Daniel Rutherford Haldane, who was for some time President of the Royal College of Physicians of Edinburgh. In response to a request by that body he represented the College in the General Council of Medical Education and Registration in the United Kingdom. He died at his residence in Edinburgh on Tuesday last.

THE annual Conference of the National Union of Elementary Teachers, which has met this week at Portsmouth, has been remarkably successful. It has been attended by about 400 delegates from the different affiliated associations, and by a number of individual members. In his inaugural address, Mr. Girling, the President, made some sensible remarks on technical education in elementary schools. Handicrafts could not be taught in elementary schools, but he was decidedly of opinion that our system of primary education ought to be better adapted to fit children for work when they leave school. He testified to the enterprise and public spirit of the City Guilds, and their Secretary, Sir Philip Magnus, who had started handicraft classes for elementary teachers in London. But he would ask them to co-operate in helping to make our educational system a more rational one. Then the teachers would have most valuable aid in preparing the future working-men of the country on intelligent lines, and the technical training of children, now so well begun in our infant-schools through the medium of kindergarten exercises, might be carried still further in the senior schools. At the meeting on Tuesday, a resolution was unanimously passed in favour of the appointment of a Minister of Education. Mr. Salmon, by whom this resolution was proposed, maintained that many educational questions of the highest importance could be adequately settled only by a Minister of much ability and wide experience, invested with large authority and bearing direct and undivided responsibility. Given such a Minister, with great power and noble opportunities, they could justly look to him for great efforts and noble issues.

THE fourth Bulletin of Miscellaneous Information, issued from the Royal Gardens, Kew, contains papers on Manilla hemp, plantain and banana fibre, and pine-apple fibre. Manilla hemp is one of the most important of cordage fibres, and the whole supply comes from the Philippine Islands. Everything made from it can be easily converted into paper of excellent quality. A plant of Manilla hemp may be seen in the Palm House at Kew; and sets of exhibits in the Kew Museum, No. 2, include the raw fibre, cables, ropes, twine, fine muslin fabrics, "half-stuff," and paper of all kinds, the latter being made from old Manilla ropes. Manilla hemp plants have been introduced from Kew to Jamaica, and to other portions of the West Indies. In favourable situations they grow well, but not so readily as the ordinary bananas and plantains. As the fruit is valueless, they can only be grown for the sake of the fibre, and this alone does not appear to offer sufficient inducement to plant up large areas.

AN Exhibition of the products of the Philippine Archipelago is to be opened at Madrid on June 1. It is to be divided into eight sections, with corresponding sections in the Central Commission at Manilla. Amongst these the following are of specially scientific interest:—(1) For the study of the geography, meteorology, terrestrial magnetism, orography, hydrography, anthropology, geology, and mineralogy of the Philippines; (4) the botanical geography of the archipelago, its fauna and flora; (8) general education, public instruction, and the arts and sciences in the Philippines generally. Sub-commissions have been appointed in all the chief places in the archipelago to collect objects for exhibition and information, to be forwarded to the Central Commission, and thence to Madrid.

DURING the next three months a course of lectures on zoology will be delivered at the Zoological Gardens, Regent's Park, by Prof. Beddard. The lecturer will try to make the subject intelligible and attractive to young people, and as the cost will not exceed the bare price of admission to the Gardens, it may be hoped that the course will be largely attended. The arrangements have been made by the Association for the Extension of University Education.

A SMALL Industrial Exhibition was opened on Tuesday last at the Flora Gardens Board School, Hammersmith. Its object is to encourage home industries among the poor.

THE twelfth annual meeting of the members of the Sunday Society was held on Monday, April 4, at the Conduit Street Galleries, Mr. R. Carter in the chair. Mr. Mark H. Judge, Hon. Sec., read the annual report, which claimed for the past year that never before had there been so many or such decisive expressions of public opinion in favour of the Society's object.

A REMARKABLE illustration of the puzzling migratory habits of the herring has just been observed on the south-west coast of Norway, at the so-called Jæderen, between the towns of Stavanger and Egersund. This district used to be one of the richest herring-fishing grounds in Norway during the spring, but about twenty-five years ago the fish suddenly and completely disappeared from the coast. Last month enormous shoals once more came under shore, first "striking land" at the same spot as in former times. The quality of the herring is exactly the same as it was twenty-five years ago, and the shoals were accompanied by numerous "herring" whales.

THE first and second parts of a Catalogue of the remains of Siwalik Vertebrata contained in the Geological Department of the Indian Museum, Calcutta, have been sent to us. The work is compiled by Mr. Richard Lydekker, who says that the magnificent Siwalik collection in the Indian Museum is equalled only by that of the British Museum.

AN Exhibition of Seeds will take place at Trondhjem, from July 4 to 10, in connection with the eighth general Norwegian Agricultural Meeting. At the same time, lectures on the subject will be delivered to the meeting, and a Fisheries Exhibition will also be held.

Dr. Franz Boas, who visited the Indian tribes of British Columbia in the autumn of 1886, has presented in a preliminary Report some of the results of his journey. The large wooden huts of these tribes, their canoes, their fishing-gear, and hunting-methods have often been described, but Dr. Boas points out that their traditions, religious ideas, and social organisation are not equally well known. The principal figure in the mythology of several of them is a raven, who created all things, not for the benefit of mankind, but "in order to revenge himself." Cannibalism is practised by some tribes in connexion with the winter dances; and there is a Kwakiutl tradition, to the effect that one of their ancestors descended from heaven, wearing a ring of red-cedar bark, and taught the people the cannibal ceremonies. These ceremonies have been adopted only in part by the Qomoks, who content themselves with eating "artificial" bodies, which they prepare "by sewing dried halibut to a human skeleton." Among the Tsimpshian, the Tlingit, and the Haida, children belong to the mother's gens; among the Kwakiutl and Selish tribes they belong to the gens of the father. In some tribes there are as many as from fifteen to twenty gentes. Members of the same gens are not allowed to intermarry.

A work on "Physiological Psychology," by Prof. George T. Ladd, of Yale, will shortly be published. The writer, according to *Science*, maintains "a philosophical and psychological stand-point, while admitting to their proper place the conclusions reached by physiology respecting the nature and functions of the nervous system."

The new numbers of "Studies in Microscopical Science," edited by Mr. A. C. Cole, deal with defoliation, spermatozoa in the Invertebrata, acute parenchymatous nephritis, fibrosis of kidney, and microbes.

The seventh Deutsche Geographentag will be held at Carlsruhe to-day. The chief papers will relate to the German African colonies.

Shocks of earthquake were felt at Friedau (Carniola) on March 27, and at Travnik, in Bosnia, on March 31, at 3.30 a.m. In the night of April 1 there was a severe shock at Forli, in Italy.

We have received from the Johns Hopkins University a new number (vol. iii. No. 9) of the series of "Studies from the Biological Laboratory." These "Studies," issued from time to time, contain most of the original scientific papers published by members of the Biological Department of the University. The editor and associate-editor are Dr. H. Newell-Martin and Dr. W. K. Brooks. The present number is a paper, by Dr. J. R. Duggan, on the influence of alcohol on the conversion of starch by diastase.

In a statistical work which is being published, M. E. Levasseur, of Paris, shows that the chances of living long at any given age are much greater now in France than they were before 1789. Of 2000 infants (under one year) 1186 survived in 1789; 1460 survive at present. In 1789, 738 persons out of 2000 reached the age of 40; the number now is 1110. In 1789, 144 persons out of 2000 lived to the age of 75; the number now is 360. The death-rate of France is much the same as that of England, being rather superior at some ages, and inferior at others.

Dr. Dudgeon, of Pekin, has at last published in Chinese a complete work on anatomy, at which he has been working for some years past. The printing was done by the press of the Tung-Wên or Foreign Language College, and the whole expense was borne by the Chinese Government. In accordance with Eastern custom, the title-page of the book is written by one of the Chinese Ministers who is celebrated for his beautiful calligraphy, and there are several prefaces by some of the highest officials of the Empire commending the work to the study of their countrymen. There are in all six volumes, two containing the illustrations, six hundred being plates. The latter were cut on blocks by native artists. Copies were presented to all the Ministers and other high officials. The companion work on physiology is almost ready for the press.

In an article on "The Phylogeny of the Camelidæ," lately printed in the *American Naturalist* extra, Mr. E. D. Cope points out that the development of the camel in North America presents a remarkable parallel to that of the horse. The ancestors of both lines appear together in the Wasatch or lowest Eocene, and the successive forms develop side by side in all the succeeding formations. Both lines died out in North America, and of the two, the camels only have certainly held their own in South America. The history of the succession of horses in Europe, although not so complete as that in America, extends over as wide a period of time. Not so with the camels. There is no evidence of the existence of the camel line in the Old World before the late Miocene epoch; and so far as the existing evidence goes, the New World furnished the camel to the Old.

In the *American Meteorological Journal*, Mr. M. W. Harrington is giving a full and very interesting account of the Chinook winds. The "Chinooks" are warm, dry, westerly or northerly winds occurring on the eastern slopes of the mountains of the north-west, beginning at any hour of the day, and continuing from a few hours to several days. Mr. Harrington says they may occur when a cyclone or anticyclone passes on such a course that the air is forced over the mountains from the western to the eastern slope. They are, therefore, winds similar to the "föhn" of Switzerland. In adding them (as Mr. G. M. Dawson, of the Geological Survey of Canada, had already done) to the class of winds of which the "föhn" is the type, Mr. Harrington points out that he is simply adding another to an already extensive list. Dr. Jelinek, in 1867, called attention to the fact that winds on the eastern slopes of the Caucasus were of this character. A similar wind occurs under the lee of the Elburz Mountains. Trebizond is in the lee of a high range of mountains, and has similar winds. They are common on the north side of the Pyrenees, and on the south coast of the Bay of Biscay. A similar wind has long been known in West Greenland, and Hoffmeyer proved, some years ago, that it is of the same character as the "föhn." It has been felt as far north as 82¼° of latitude. Mr. Scott suggests that the hot winds of South Africa and parts of Australia are of the same character, while the analogy is proved complete for the hot "north-westers" of the Canterbury Plains of New Zealand.

The first number of the American journal *The Stevens Indicator*, in its new form as a quarterly, contains an article giving a glowing account of the general prosperity of the Stevens Institute. The advance secured is attributed mainly to the wise and energetic leadership of President Morton. "To him," says the *Indicator*, "belongs the honour of realising, more than twenty years ago, when the Institute was first planned, that it would find its most useful work in the then almost unoccupied field of mechanical engineering, and that to this work it should confine, for a series of years at least, all its resources and efforts. How well the plans have succeeded is borne out by the long list of graduates who have been sent forth into positions of honour and trust, of influence and remuneration, by Stevens Institute during the last twelve years."

Capt. Gates, of the ship *L. Schepp*, has reported to the U.S. Hydrographic Office that on April 19, 1886, when he was off Cape Horn, on a voyage from San Francisco to Liverpool, the temperature of the water suddenly rose from 42° to 44°. Thinking that the vessel was too close in shore, he hauled off three points, and, after he had stood four hours on this course, he found that the temperature had fallen to 42°. On a previous voyage Capt. Gates noticed this warm belt.

COMMISSIONER COLMAN, of the Department of Agriculture in the United States, has issued a Circular relating to the so-called Australian rabbit. He points out that this animal—the common rabbit of Europe—has been very mischievous in Australia, and expresses his belief that its introduction into America would be an unnecessary and hazardous experiment. Mr. Colman is of opinion that Congress should pass a law conferring upon the Commissioner of Agriculture the power to prevent the landing of any animal, bird, or other pest that might be injurious to agriculture; and he cites the case of the English sparrow as an example of the harm that may be done by species taken without due consideration from the Old World to the New.

THE Swedish Government is anxious to acquire a colony in Africa, and is consequently preparing an Expedition under the direction of Lieut. A. Wester, formerly Chief of the Congo Station, Leopoldville. At the last meeting of the Stockholm Society of Anthropology and Geography, Lieut. Wester reported on the subject. The Expedition may probably start next summer, and will be absent about a year, making Cameroon its base of operations. The cost will be about 160,000 kroner (8000*l.*).

MR. PAUL BEDFORD ELWELL will publish shortly, with Messrs. Whittaker and Co., an English translation of Gaston Planté's work on "The Storage of Electrical Energy."

THE eighth volume of the Journal of the Royal Horticultural Society, just issued, consists of a valuable Report on the effects of the severe frosts on vegetation during the winters of 1879–80 and 1880–81. The Report has been prepared by the Rev. Geo. Henslow, Honorary Secretary to the Scientific Committee of the Royal Horticultural Society. Most of the facts were obtained by means of schedules issued in 1880 and 1881.

A WORK entitled "The Australasian Federal Directory of Commerce, Trades, and Professions," will shortly be published in London under the direction of Mr. J. W. F. Rogers, of Melbourne and Sydney. It has been compiled by the assistance of some thousands of persons, many of them Colonial Government officials, and will give both in an alphabetic and a classified form the business addresses for over three thousand Australasian towns, large and small. Reviews of the social and commercial development of the eight colonies of this group will appear in the Directory, with maps and gazetteer.

AN ingenious system of gas-lighting by electricity has been introduced by Messrs. Woodhouse and Rawson. Gas can be turned on, lit, and turned off from any convenient position irrespective of where the gas-fittings are placed. The principle of attachment is like that of the portable electric gas-lighter—*i.e.* the gas is lighted by an electric spark—but the general arrangements are for permanent fitting.

WE have received the fifth and sixth parts of the fourth volume of Dr. L. Rabenhorst's elaborate "Kryptogamen-Flora von Deutschland, Oesterreich, und der Schweiz." The subject dealt with is Bryineæ: Stegocarpæ (Acrocarpæ). The text is finely illustrated.

THE second part of the Report for 1885 of the Chief Signal Officer of the United States, is a separate treatise by Prof. William Ferrel, entitled, "Recent Advances in Meteorology, systematically arranged in the form of a Text-book, designed for use in the Signal Service School at Fort Meyer, and also for a Hand-book in the Office of the Chief Signal Officer." It is an octavo volume of 440 pages, and is published by the U.S. Government.

THE sixty-fourth number of the Journal of the Society of Telegraph-Engineers and Electricians, contains "The Pre-Determination of the Characteristics of Dynamos," by Mr. Gisbert Kapp; "Some Experiments on Secondary Cells," by Mr. James Swinburne; and "Some Magnetic Problems," by Prof. George Forbes. Reports of the discussions on these papers are also given.

A PERMANENT matrix excluder of draught and dust has been sent to us by Mr. T. J. Porter, the inventor. The excluder is made of a special composition inclosed in long, narrow strips of warm-coloured cloth, and moulded into a suitable form. The application of hot water enables the excluder to be formed into a long, narrow, solid, and permanent matrix round doors and windows. Mr. Porter says that it makes a practically air-tight joint, and entirely precludes the passage of draught and dust between doors and their casings, and windows and their casings.

A HALIBUT weighing thirty-four pounds and measuring 41 inches in length was captured lately in the lower Potomac, near Colonial Beach. It has been preserved in alcohol by the Smithsonian Institution, and a cast has been made and placed on exhibition in the U.S. National Museum. *Science* says this is the first authentic case of a halibut in fresh water.

THE additions to the Zoological Society's Gardens during the past week include a Short-tailed Wallaby (*Halmaturus brachyurus*) from Australia, presented by Mr. Herbert Maude; an American Flying Squirrel (*Sciuropterus volucella*) from North America, presented by Mr. A. R. Verschoyle; an Egyptian Mastigure (*Uromastix spinipes*) from North Africa, presented by Mr. V. J. Chamberlain; a Nepal Hornbill (*Aceros nepalensis*) from Nepal; a Tuberculated Iguana (*Iguana tuberculata*) from the West Indies, deposited; a Burchell's Zebra (*Equus burchelli*) from South Africa; two Adorned Ceratophrys (*Ceratophrys ornata*); an Anaconda (*Eunectes murinus*) from South America, purchased; a Rhesus Monkey (*Macacus rhesus*), a Sambur Deer (*Cervus aristotelis*), two Collared Fruit-Bats (*Cynonycteris collaris*), born in the Gardens.

OUR ASTRONOMICAL COLUMN

ORBIT OF THE BINARY STAR 14 (*i*) ORIONIS.—In the *Monthly Notices* for March, Mr. J. E. Gore publishes elements of the orbit of this binary, which is identical with O Σ 98. Mr. Gore's results, which he regards as only provisional, give a period of 190·48 years, time of periastron passage 1959·05, eccentricity 0·2465, and semi-axis major 1″·22. A comparison of places computed from these elements with the observations extending from 1844 to 1887, shows considerable discordances in the position-angles, whilst the distances agree very closely. The orbit of this double star does not appear to have been previously computed.

THE WASHINGTON OBSERVATORY.—Capt. R. L. Phythian, U.S.N., the Superintendent of the U.S. Naval Observatory, has published the programme of work to be pursued at the Observatory during the year 1887. From it we learn that with the 26-inch equatorial the observations of double stars, of the fainter stars in the Pleiades, and of the conjunctions of the five inner satellites of Saturn with the minor axis of the ring, and of the angles of position and distances of Hyperion will be continued during the year. The small equatorial will be used for observations of comets and of occultations of stars by the moon, as well as of stars and asteroids required for purposes of identification. With the transit-circle it is proposed to complete the observations of miscellaneous stars for the forthcoming transit-circle catalogue and also to observe the sun, moon, planets (major and minor), and stars of the American Ephemeris. Photographs of the sun will be taken daily, when practicable, with the photo-heliograph of the Transit of Venus Commission pattern.

NAMES OF MINOR PLANETS.—Minor planets Nos. 263 and 265 have been named *Dresda* and *Anna* respectively.

ASTRONOMICAL PHENOMENA FOR THE WEEK 1887 *APRIL* 17–23

(For the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is here employed.)

At Greenwich on April 17

Sun rises, 5h. 2m.; souths, 11h. 59m. 33·9s.; sets, 18h. 57m.; decl. on meridian, 10° 28′ N.: Sidereal Time at Sunset, 8h. 39m.

Moon (New on April 23) rises, 3h. 3m.; souths, 7h. 53m.; sets, 12h. 49m.; decl. on meridian, 14° 2′ S.

Planet	Rises h. m.	Souths h. m.	Sets h. m.	Decl. on meridian ° ′
Mercury	4 29	10 22	16 15	2 9 S.
Venus	6 6	14 5	22 4	20 54 N.
Mars	5 8	12 7	19 6	10 45 N.
Jupiter	19 11*	0 20	5 20	10 37 S.
Saturn	9 20	17 29	1 38*	22 26 N.

* Indicates that the rising is that of the preceding evening and the setting that of the following morning.

April	h.	
18	21	Mercury at greatest elongation from the Sun, 27° west.
20	21	Mercury in conjunction with and 0° 31′ north of the Moon.
21	11	Jupiter in opposition to the Sun.

Variable Stars

Star	R.A. h. m.	Decl. ° ′		h. m.	
U Cephei	0 52·3	81 16 N.	Apr. 19,	4 42	*m*
Algol	3 0·8	40 31 N.	,, 17,	20 45	*m*
δ Libræ	14 54·9	8 4 S.	,, 20,	21 3	*m*
			,, 23,	4 54	*m*

			and at intervals of	20 8	
W Sagittarii	17 57·8	29 35 S.	Apr. 20,	22 0	*M*
β Lyræ	18 45·9	33 14 N.	,, 20,	0 0	*M*
S Vulpeculæ	19 43·8	27 0 N.	,, 20,		*m*
S Sagittæ	19 50·9	16 20 N.	,, 18,	22 0	*m*
δ Cephei	22 25·0	57 50 N.	,, 20,	4 0	*M*
			,, 23,	22 0	*m*

M signifies maximum; *m* minimum.

Meteor-Showers

The most interesting shower of the week is that of the *Lyrids*, April 18–20, R.A. 268°, Decl. 33° N. Other showers are as follows:—Very slow meteors from a radiant between Bootes and Virgo, R.A. 213°, Decl. 9° N.; very swift meteors from near π Herculis, R.A. 255°, Decl. 37° N., and from Vulpecula, R.A. 299°, Decl. 24° N.

VALENCY AND RESIDUAL AFFINITY[1]

I.

In my address to the Chemical Section of the British Association at Aberdeen, I specially called attention to the "affinity" of *negative* elements—chlorine, oxygen, sulphur, &c.—for negative elements; and I sought to show that the formation of so-called *molecular compounds* is largely, if not entirely, an outcome of this peculiarity of negative elements. I also ventured to suggest "that in electrolysing solutions, the friction arising from the attraction of the ions for each other is perhaps diminished, not by the mere mechanical interposition of the *neutral* molecules of the solvent—in the manner suggested by F. Kohlrausch—but by the actual attraction exercised by these molecules upon the negative ion in virtue of the affinities of the negative radicles." In this passage I but vaguely hinted at a modification of the current theory of electrolysis which had occurred to me: as further consideration of the question, especially of Ostwald's electro-chemical studies, has strengthened my views, I am led to think that it may be justifiable to submit them for discussion.

It is usual to divide bodies into three classes according to the mode in which they are acted on by an electromotive force: metals forming one class, electrolytes a second, and dielectrics a third. In making this division, perhaps the fact is not sufficiently borne in mind that some compounds—silver chloride, for example—are *per se* electrolytes, while others—such as hydrogen chloride and water—are *individually* dielectrics, but behave as electrolytes when conjoined. On this account, it appears to me desirable to distinguish between—

(*a*) *Metals.*

(*b*) *Simple* electrolytes—compounds like silver chloride which in the pure state are electrolytes.

(*c*) *Pseudo*-dielectrics — compounds like water, hydrogen chloride, and sulphuric acid, which behave as dielectrics when *pure*, but as electrolytes when mixed with other members of their own class. Conducting mixtures of members of this class may conveniently be termed *composite electrolytes.*

(*d*) Dielectrics.

Simple Electrolytes.—It is undoubtedly a fact that only a limited number of binary compounds are simple electrolytes; and it is especially noteworthy that, with the single doubtful exception of liquefied ammonia, no hydrogen compound—whether binary or of more complex composition—can be classed with the simple electrolytes. Indeed, all the simple electrolytes with which we are acquainted are either compounds, such as the *metallic* chlorides; or *metallic* salts—nitrates, sulphates, &c. Including metallic chlorides and their congeners and the corresponding oxides and hydroxides among salts—regarding water as an acid, in fact—and denying the title of salts—hydrogen salts—to the acids, Hittorf's proposition (*Wied. Ann.*, 1878, iv., p. 374), "Electrolyte sind Salze" may be safely upheld. But only some of the binary metallic salts are electrolytes: beryllium chloride, for example, belongs to the class of "pseudo-dielectrics" (Nilson and Petterson, *Wied. Ann.*, 1878, iv., p. 565; Humpidge, Phil. Trans., 1883, p. 604); and in the case of those elements which readily form two classes of salts—so-called *ous* or *proto*-salts and *ic* or *per*-salts, the *ous* compounds alone appear to be electrolytes.

It is highly remarkable that whereas fused silver chloride is easily decomposed on passage of a current of low electromotive force, hydrogen chloride is a "pseudo-dielectric" which forms when coupled with the "pseudo-dielectric" water a readily conducting "composite electrolyte", while mercuric chloride conducts with great difficulty—possibly not at all when pure—not only in the fused state, but even when coupled with water. No explanation of these facts seems to be afforded by thermo-chemical data.

The consideration of these and other similar cases, I think, can but lead to one conclusion: that electrolysability is conditioned both by the nature of the elements in the compound and its molecular structure.

The remarkable difference in the electrical behaviour of two compounds of the same element, such as stannous chloride, in which the ratio of tin to chlorine atoms is as 1 to 2, and stannic chloride, in which Sn : Cl = 1 : 4—the one being a simple electrolyte, the other a pseudo-dielectric, if indeed it be not a dielectric—would appear almost to justify the conclusion that in the case of per-salts such as stannic chloride the metal is, as it were, enveloped in a non-conducting sheath of the negative radicle. But whether this be so or not, if—as appears to be the case—all simple electrolytes are *metallic* compounds, and if only proto-salts are electrolytes, may it not be that electric conduction in simple electrolytes is of the nature of ordinary metallic conduction, differing from it only in the circumstance that the compound is decomposed as a consequence of the passage of the current?

This would lead to the conception of an electrolyte as being a metallic compound of such elements, and so constituted, that electric conduction may take place through its mass in a manner similar to that in which it takes place through a mass of metal: in fact, through the agency of its metallic atoms. On this view, it is essential that the metallic atoms in the molecules comprising a mass of an electrolyte should be in proximity—as they probably are in proto-salts, but not in many per-salts. The conductivity of two-metal alloys is in many cases much less than that of either of the contained metals: for example, the conductivity of the alloy $SnCu_4$ is about one-fourth that of tin and about one-thirtieth that of copper. The specific conductivity of metals may, therefore, be much reduced by association with one another; and this being the case, it appears probable that the specific conductivity of a metal would be still more reduced by association with a non-metal, and that if the metal were one of low specific conductivity, it might thus practically become altogether deprived of conducting power: perhaps the "exceptional" behaviour of mercuric and beryllium chlorides is to be explained by considerations such as these.

---

[1] Revision and extension of a paper by Prof. H. E. Armstrong, F.R.S., communicated to the Royal Society last year.

To discuss such questions at all satisfactorily, however, we require to know much more of the electrical behaviour of *pure* fused salts. It is surprising how little accurate knowledge we possess on this subject.

Composite Electrolytes.—I assume it to be admitted that neither water nor liquid hydrogen chloride, for example, is an electrolyte, although an aqueous solution of hydrogen chloride conducts freely, and is electrolysed by an electromotive force of but little more than a volt.

The theory put forward by Clausius in 1857 in explanation of electrolysis (cf. Clerk Maxwell's "Elementary Treatise on Electricity," p. 104), has been widely accepted by physicists; but it appears to me that, on careful consideration of the evidence, and especially of recent exact observations on conditions of chemical change, it must be admitted, as I have elsewhere contended (B. A. Address), that proof is altogether wanting of the existence of a condition such as is postulated by Clausius. Moreover, it has been shown by Hittorf that cuprous and silver sulphides, and by F. Kohlrausch that silver iodide, all undergo electrolysis in the *solid* state: the partisans of the dissociation hypothesis would, I presume, scarcely contend that it is easily applicable to such cases as these. It also does not appear to afford any explanation of the *abrupt* change in conductivity which occurs in solid silver iodide and sulphide as the temperature is raised; nor of the peculiar variation in conductivity which is observed on diluting sulphuric acid with water

Again, I venture to think that the conductivity of a *mixture* of compounds which themselves have little or no conducting power is accounted for in but an unsatisfactory and insufficient manner by the hypothesis put forward by F. Kohlrausch (*Pogg. Ann.*, 1876, clix., p. 233); there appears to be *far too great a difference* in the behaviour of the pure compounds, water and liquid hydrogen chloride for example, and of a mixture—no decomposition apparently of either *compound* being effected by any electromotive force short of that which produces disruptive discharge, although the *mixture* of the two will not withstand an electromotive force of little more than a volt. Influenced by these considerations, I am led to conclude that there is no satisfactory evidence that the constituents of the electrolyte either are free prior to the action of the electromotive force, or are primarily set free by the effect produced by the electromotive force upon either member *separately* of the *composite* electrolyte; but that an additional influence comes into play, viz. that of the one member of the composite electrolyte upon the other while both are under the influence of the electromotive force. This influence, I imagine, is exerted by the negative radicle of the other member. Assuming. for example, that in a solution of hydrogen chloride in water the oxygen atom of the water molecule is straining at the chlorine atom of the hydrogen chloride molecule, if when subjected to the influence of an electromotive force the molecules are caused to flow past each other—the phenomena of electric endosmose may be held to afford evidence that in composite electrolytes the molecules are thus set in motion—it is conceivable that this influence, superadded to that of the electromotive force upon the electrolyte, may bring about the disruption of the molecule and conduction: in short, that a state may be induced such as Clausius considers is the state prior to the action of the electromotive force.

A large amount of most valuable information on the connexion of dilution and electrical conduction in aqueous solutions has been recently published by Arrhenius, Bouty, F. Kohlrausch, and Ostwald. In his most recent paper, Ostwald (*Journal für praktische Chemie*, 1885, xxxii., p. 300) has given the results of his determinations of the *molecular conductivity* in the case of no less than about 120 different acids; and it appears to me that many—indeed all—of his observations afford most distinct evidence in favour of the view I have expressed above. The general result of his investigation is that the molecular conductivity increases with dilution: in other words, that the dissolved substance exercises a greater specific effect, finally attaining a maximum; it then diminishes, but he believes this to be due to impurities in the water, especially to neutralisation of the acid by traces of ammonium carbonate. The maximum, he appears to think, would be the same for all acids if the dilution could only be pushed far enough: in the case of monobasic acids it is about 90 (arbitrary units); it is twice this in the case of dibasic, thrice in the case of tribasic, and so on.

I will quote first his results in the case of solutions of hydrogen chloride, bromide, iodide, fluoride, and silicon fluoride. v is the volume in litres which contains a weight in grammes corresponding to the formula of the dissolved substance—36·4 grammes of hydrogen chloride, for example.

v	HCl	HBr	HI	HF	H_2SiF_6
2	77·9	80·4	80·4		47·81
4	80·9	83·4	83·2	6·54	57·29
8	83·6	85·1	84·9	7·59	62·20
16	85·4	86·6	86·4	10·00	67·08
32	87·0	87·9	87·6	13·14	71·52
64	88·1	88·9	88·7	17·38	75·61
128	88·7	89·4	89·4	23·11	79·22
256	89·2	89·6	89·7	30·30	83·39
512	89·6	89·7	89·7	39·11	91·62
1024	89·5	89·5	89·3	49·49	109·5
2048	89·5	88·9	89·0	59·56	144·0
4096	88·6	87·6	87·8	69·42	187·1
8192					226·6
16384					258·6
32768					282·6

It will be observed that hydrogen chloride, bromide, and iodide practically behave alike; the numbers for the chloride are, however, slightly lower than those for the bromide and iodide, and the maximum is not reached quite so soon in the case of the chloride. Hydrogen fluoride is altogether different; its molecular conductivity is exceedingly low to begin with, and is considerably below the maximum even when $v = 4096$. But I would call special attention to the numbers for hydrogen silicon fluoride, which is commonly regarded as a dibasic acid: at first, as Ostwald says, it behaves as a monobasic acid of moderate strength—iodic acid, for example; but the maximum for monobasic acids being exceeded, the molecular conductivity increases more and more rapidly, ultimately exceeding the treble value, 270. It must be supposed that it undergoes decomposition in accordance with the equation—

$$H_2SiF_6 + 2H_2O = SiO_2 + 6HF.$$

The noteworthy point is *the large excess of water* required to initiate this change: when $v = 16$ the solution contains less than 1 per cent. H_2SiF_6, and at this point, according to Ostwald, decomposition probably begins; but that it is far from complete even when a very much larger excess is present is evident from the fact that the maximum when $v = 32,768$ is 282 and not above 400.

Now it is well known that hydrogen chloride, bromide, and iodide are, practically speaking, perfect gases under ordinary circumstances: in other words, masses of these gases would mainly consist of molecules such as are represented by the formulæ HCl, HBr, and HI. It has been proved, however, by Mallet, that hydrogen fluoride at temperatures near to its boiling-point mainly consists of molecules of the formula H_2F_2. In the aqueous solution the molecules would be brought more closely together, and therefore it is probable that, even in the case of hydrogen chloride, bromide, and iodide, a certain proportion of more complex molecules would result: the relatively high boiling-point of hydrogen fluoride (19°·4) renders it probable that in the liquid state this compound would at least partially consist of molecules more complex even than is represented by the formula H_2F_2. On the hypothesis put forward in this paper, the influence exercised by the one member of the composite electrolyte upon the other member during electrolysis is at all events mainly exercised by their respective negative radicles, and the extent of the influence thus mutually exerted by these radicles would depend on the extent to which they are still possessed of "residual affinity." If the hydrogen chloride, bromide, and iodide are present chiefly as simple molecules, they should exert, *ab initio*, almost the full effect which they are capable of exerting; and the chief effect of dilution being to decompose the more complex molecules, conductivity should increase to but a slight extent if the extent to which simplification can take place be but small. On the other hand, if owing to the formation of molecular aggregates the residual affinity be more or less exhausted, the initial conductivity will be low, and it will increase on dilution only in proportion as these aggregates become broken up.

It appears to me that the behaviour of the four hydrides under discussion is absolutely in accordance with these requirements of the hypothesis. Evidence of the same kind is afforded by all of Ostwald's results.

The behaviour of solutions of neutral metallic salts on dilution is very similar to that of acids; abundant proof of this is afforded especially by F. Kohlrausch's refined measurements, of which an account has recently been published (*Wied. Ann.*, 1886, xxvi., p. 162). I venture to think that a similar explanation to that above given for oxides will apply to salts; and also that the low molecular conductivities of salts as compared with corresponding acids may be regarded as confirmatory of my hypothesis. I think we must admit that the metals generally have less affinity than hydrogen for negative radicles; if this be granted, we have at once an explanation of the fact that metallic salts are mostly fixed solids, few of which are more than moderately soluble in water while many are very difficultly soluble or insoluble, whereas the corresponding acids are mostly volatile and readily soluble in water, if not miscible with it in all proportions. The affinity of the negative radicles being less exhausted by union with metals than with hydrogen, the fundamental molecules of salts are more prone to unite together to form complex aggregates.

Arrhenius, who has studied the electrical behaviour of solutions of a number of salts, attributes the change observed in molecular conductivity on dilution—as I have done—to molecular changes; but his deductions are all based on the acceptance of the Williamson-Clausius hypothesis of dissociation.

My hypothesis would also account for the increase in conductivity in composite electrolytes with rise of temperature. It is true that as temperature rises the influence which individual molecules exert upon each other would be lessened; but, on the other hand, the complex aggregates would become more and more completely resolved into their fundamental molecules, the velocity of molecular motion would increase, and the tendency of the constituent atoms to remain united would be lessened. From this point of view the determination of the coefficient of change of conductivity with temperature in the case of substances whose molecular conductivity increases considerably on dilution in comparison with allied compounds which exhibit only a slight variation in molecular conductivity on dilution affords an interesting subject for investigation. F. Kohlrausch has already pointed out (*Pogg. Ann.*, 1875, cliv., p. 236) that in the case of all neutral salts, "der Einfluss der Temperatur auf das Leitungsvermogen mit wachsender Verdünnung sich Anfangswerthen nahert, die zwischen engen Gränzen liegen;" and the experiments of F. Kohlrausch and Nippoldt on solutions of sulphuric acid (*ibid.*, 1869, cxxxviii., p. 286) show that the resistance diminishes to a much greater extent for equal increments of temperature in concentrated than in dilute solutions.

As concentrated solutions would be richer in complex aggregates than dilute solutions, these results are in entire accordance with my hypothesis: it does not appear to me that they can be satisfactorily interpreted in terms of the dissociation hypothesis.

In cases where the influence of the one member of the composite electrolyte upon the other is but slight, it may happen that the effect of temperature in diminishing this influence will outweigh that due to molecular simplification, and that, in consequence, conductivity will diminish with rise of temperature; a mixture of alcohol and ether would appear to furnish an example of this kind: according to Pfeiffer's recent observations (*Wied. Ann.*, 1886, xxvi., p. 216), such a mixture behaves as a metallic conductor of very high resistance.

The increase in conductivity of graphite and gas-retort carbon on heating, and the effect of light on the conductivity of (? impure) selenium and some other substances (Shelford Bidwell, Phys. Soc. Proc., pp. 122, 256), appear to me to be also explicable on the assumption that in all these cases we are dealing with composite electrolytes.

If any further proof be needed of an intimate connexion between molecular composition and electrolytic conduction, it is most conclusively afforded, I think, by the observations of W. Kohlrausch on chloride, bromide, and iodide of silver (*Wied. Ann.*, 1882, xvii., p. 642). In the fused state, these compounds are better conductors than the most highly-conducting mixture of sulphuric acid and water, which of all liquids is the best conductor at ordinary temperatures; but when the change from the fused to the solid state sets in the resistance of both silver chloride and bromide suddenly increases. No such change takes place, however, in the case of silver iodide. This iodide fuses at 557° according to Rodwell, but at about 540° according to Kohlrausch; its electrical resistance increases only gradually after it has become solid, and remains almost a linear function of the temperature during an interval of 400°, until suddenly at near 150° it increases enormously, this change taking place at the moment when, according to Rodwell (Phil. Trans., 1882, p. 1153), it passes from the transparent, plastic, amorphous solid to the opaque, crystalline state, the volume increasing considerably. Kohlrausch has proved most conclusively that the solid iodide may undergo electrolysis. It would seem that almost immediately after solidification in the case of silver chloride and bromide practically the whole mass consists of complex aggregates so constituted as to be exceedingly bad conductors, but that such aggregates are formed much less readily by silver iodide.

(*To be continued.*)

THE MAZAPIL METEORIC IRON[1]

AMONG the large number of meteoric irons which have been described, only eight[2] are recorded as having been seen to fall. It is my privilege to be able to add a ninth fall to this short list, and one which may prove to be of exceptional scientific importance. This mass of meteoric iron I received in August last as a gift from my friend, Prof. José A. y Bonilla, Director of the Astronomical Observatory at Zacatecas, Mexico. He stated that it was *seen to fall* at about 9 p.m. on November 27, 1885, during the periodical star-shower of the "Bielids." Such is the unique interest of this meteorite, as shown by its history, that I have delayed announcing it until the evidence of its fall had been substantiated as thoroughly as possible.

The general freshness of surface, which shows very perfectly the flow of the melted crust; the presence of unusually large nodules of a very compact graphite; the very slight superficial oxidation, and its dissimilarity to other meteorites of the region, are all interesting features of this iron, and serve to confirm the statement of its recent fall. When received it weighed about 3950 grammes. Its present weight is 3864 grammes, or 10 pounds 4¼ ounces, troy. Its greatest length is 175 millimetres as measured diagonally across the mass. In its thickest part it measures about 60 millimetres. It could be described as a flat irregular mass, covered with deep depressions, having a smooth surface (see Fig. 1).

The evidence of the fall is set forth in the following communication from Prof. Bonilla.

(Translation).—"It is with great pleasure that I send to you the uranolite which fell near Mazapil, during the night of November 27, 1885. That you may the better appreciate the great scientific interest which this uranolite possesses, I will state that everything points to the belief that it belongs to a fragment of the comet of Biela-Gambart, lost since 1852. I here give you the history of this celestial wanderer. On December 27 (1885) I received, to my great delight, from Eulogio Mijares, who lives on the Conception Ranch, 13 kilometres to the east of the town of Mazapil, a uranolite, which he saw fall from the heavens, at nine o'clock on the evening of November 27, 1885. The fall, simply related, he tells as follows, in his own words:—

"'It was about nine in the evening when I went to the corral to feed certain horses, when suddenly I heard a loud hissing noise, exactly as though something red-hot was being plunged into cold water, and almost instantly there followed a somewhat loud thud. At once the corral was covered with a phosphorescent light and suspended in the air were small luminous sparks as though from a rocket. I had not recovered from my surprise when I saw this luminous air disappear and there remained on the ground only such a light as is made when a match is rubbed. A number of people from the neighbouring houses came running toward me and they assisted me to quiet the horses which had become very much excited. We all asked each other what could be the matter, and we were afraid to walk in the corral for fear of getting burned. When, in a few moments, we had recovered from our surprise, we saw the phosphorescent light disappear, little by little, and when we had brought lights to look for the cause, we found a hole in the ground and in it a ball of fire. We retired to a distance, fearing it would explode and harm us. Looking up to the sky we saw from time to time exhalations or stars, which soon went out, but without noise. We returned after a little and found in the hole a hot stone, which we could barely handle, which on the next day we saw looked like a piece of iron; all night it rained stars, but we saw none fall to the ground as they seemed to be extinguished while still very high up.'

[1] From the March number of the *American Journal of Science*, vol. xxxiii pp 221–26.

[2] Agram, Croatia, May 26, 1751; Charlotte, Dickson Co., Tenn., August 1, 1835; Braunau, Bohemia, July 14, 1847; Tabarz, Saxony, October 18, 1854; Victoria West, Africa, in 1862; Nejed, Arabia, spring of 1865; Nedagolla, India, January 23, 1870; Rowton, Shropshire, England, April 20, 1876. See the Catalogue of the Meteorites in the Mineral Department of the British Museum, by L. Fletcher, p. 42.

"The above is the simple recital of the ranchman, and the uranolite which fell is the one I send to you. From the numerous questions I have asked Sr Mijares, I am convinced that there was no explosion or breaking up on falling. Others who saw the phosphorescence, &c., were Luz Sifuentes, Pascual Saenz, Miguel Martinez, Justo Lopez, and some whose names I have not obtained. Upon visiting the place of the fall I was particular to examine the earth in and around the hole, and by careful search and washing the earth I found a few small bits of iron, which must have become detached from the uranolite when it penetrated the earth.

"The hole was 30 centimetres deep. Probably the light which was seen came from the volatilisation of the surface of the celestial body due to the high temperature acquired by friction with the atmosphere, and of this volatilised matter falling to the earth as an incandescent powder."

The above communication was followed by an account of the observation of the Biela meteors at Zacatecas by Prof. Bonilla and his assistants. (See Annals N.Y. Acad. Sci. 1887.)

The locality of the fall is situated in latitude 24° 35′ N. and in longitude 101° 56′ 45″ West of Greenwich.

That no explosion was heard when this iron fell, is paralleled by the account of the fall of the fifty-six pound aerolite near Wold Cottage, Yorkshire, England, on December 13, 1795. "This stone fell within 10 yards of where a labourer was at work. No thunder, lightning, or luminous meteor accompanied the fall; but in two of the adjacent villages the sounds were so distinct of something passing through the air towards Wold Cottage that several people went to see if anything extraordinary had happened to the house or the grounds" (L. Fletcher, "An Introduction to the Study of Meteorites," 1886, p. 22). Concerning the aerolites which fell at 11.50 a.m., on June 28, 1876, at Stalldalen, in Sweden, "it is remarkable that no meteor was visible at the place where the stones fell, though it was seen over nearly all Sweden."

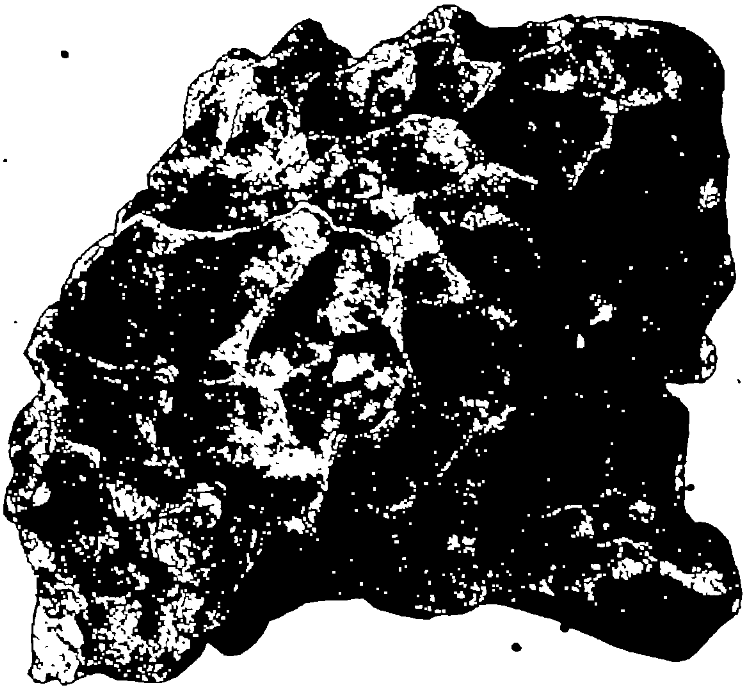

FIG. 1.—Mazapil Meteoric Iron. Weight 10 lbs. 4¼ oz. troy (⅔ natural size.)

The surface of the Mazapil iron is of great interest. The deeply hollowed depressions entirely cover the mass (see Fig. 1). A thin black crust coats the surface, and exhibits well the striæ of flow, as seen on meteorites whose fall has been observed. In eleven places nodules of graphite are noticed extruding from the surface (the engraving shows some of these), one of them is nearly an inch in diameter. The graphite is very hard and apparently amorphous; troilite and schreibersite were noticed on a section cut off for analysis and for the development of the figures of Widmanstatten. The crystalline structure (see Fig. 2) is well shown in the engraving (Ives' process) which is of natural size. The lines are somewhat similar to that of the Rowton iron in their width and distribution, and are very unlike the known Mexican irons from Toluca, &c.

In its surface and general flatness the mass bears a remarkable resemblance to the Hraschina, Agram, iron[1] which fell May 26, 1751. In its weight it is nearly like the irons of Rowton (7¾ lbs.), Charlotte (9¼ lbs.), Victoria West (6 lbs. 6 ozs.), and Nedagolla (9¾ lbs.), which were all seen to fall.

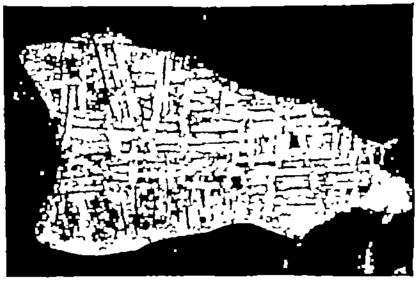

FIG. 2.—Section of Mazapil Meteoric Iron (natural size.)

---

[1] See "Beiträge zur Geschichte und Kenntniss meteorischer Stein- und Metalmassen," by Dr. Carl von Schreibers, Wien, 1820, plate viii.

Mr. J. B. Mackintosh has kindly analysed a small fragment with the following results, which, for comparison with other irons seen to fall, I have placed in tabular form :—

	Mazapil.	Rowton. Flight.	Charlotte. Smith.	Estherville.[1] Smith.
Iron.	91·260	91·250	91·15	92·000
Nickel.	7·845	8·582	8·05	7·100
Cobalt	0·653	0·371	0·72	0·690
Phosphorus ..	0·300	. . .	0·06	0·112
	100·058	100·203	99·98	99·902

Carbon is distributed all through the iron between the crystalline plates, and it is noteworthy that this element was observed with the spectroscope as present, in the "Bielids" of November 27, 1885. Chlorine is also present and shows itself by a slight superficial deliquescence. Of this latter I will state that most of the surface oxidation of the ferrous chloride has occurred since August last. As yet no tests have been made to ascertain the amount of occluded gases, or to analyse the graphite nodules, and it is probable that this might only lead to results similar to those already obtained. Over the mass, where the crust has been accidentally removed, the lines of crystallisation (Widmanstatten figures) can readily be traced without etching the surface. The abrasion due to impact was very slight.

In conclusion, we cannot, from the very circumstantial account of the fall, and the corroborative evidence of the iron itself, which in several particulars contains heretofore unrecorded observances, decline to receive this meteorite as the ninth recorded fall of an iron mass to the earth ; and perhaps at another period of the November "Bielids" this fall will be confirmed in all its interesting details. The interest connected with this meteorite, because of its beautifully marked and fresh surface, is enhanced by the concurrence of the time of its fall with the shower of the Biela meteors.

I wish to express here my deep obligation to Prof. Bonilla for the interesting data concerning this meteorite and for the gift of the meteorite itself, and to Mr. Mackintosh also for his kind interest in making the chemical analysis.

WILLIAM EARL HIDDEN

SOCIETIES AND ACADEMIES

LONDON

Royal Society, March 24.—"On Ellipsoidal Current Sheets." By Horace Lamb, M.A., F.R.S.

The paper treats of the induction of electric currents in an ellipsoidal sheet of conducting matter whose conductivity per unit area varies as the perpendicular from the centre on the tangent plane, or (say) in a thin shell of uniform material bounded by similar and coaxial ellipsoids. The method followed is to determine in the first instance the normal types of free currents.

When the normal types and their persistencies have been found, it is an easy matter to find the currents induced by given varying electromotive forces. Supposing that we have an external magnetic system whose potential varies as e^{ipt}, we can determine a fictitious distribution of current over the shell which shall produce the same field in the interior. If $\bar{\phi}$ denote the current-function for that part of the distribution which is of any specified normal type, ϕ that of the induced currents of this type, it is shown that

$$\phi = -\frac{ip\tau}{1 + ip\tau}\bar{\phi},$$

where τ is the corresponding persistency of free currents. When $p\tau$ is very great this becomes

$$\phi = -\bar{\phi},$$

in accordance with a well-known principle.

This method can be applied to find the currents induced by rotation of the shell in a constant field, it being known from Maxwell's "Electricity," § 600, that the induced currents are the same if we suppose the conductor to be fixed, and the field to rotate in the opposite direction. When the conductor is symmetrical above the axis of rotation, the current-function of any normal type contains as a factor cos $s\omega$ or sin $s\omega$, where ω is the azimuth, and s is integral (or zero). When we apply Maxwell's artifice, the corresponding time-factor is e^{ispt}, where p is the angular velocity of the rotation ; and we easily find that the system of induced currents of any normal type is fixed in space, but is displaced relatively to the field through an angle,

$$\frac{1}{s}\text{ arc tan } ps\tau$$

in azimuth, in the direction of the rotation.

In the most important normal types the distribution of current over the ellipsoid is one which has been indicated by Maxwell ("Electricity," § 675) as giving a uniform magnetic field throughout the interior.

In the higher types the current-function ϕ is a Lamé's function, degenerating into a spherical harmonic when two of the axes of the ellipsoidal shell are equal. Of the special forms which the conductor may assume, the most interesting is that in which the third axis (that of symmetry) is infinitesimal, so that we have practically a circular *disk*, whose resistance ρ' varies according to the law

$$\rho' = \rho_0' \sqrt{\{1 - r^2/a^2\}},$$

where ρ_0' is the conductivity at the centre, a is the radius, and r denotes the distance of any point from the centre. In the most persistent type

$$\tau = \frac{\pi^2 a}{2\rho_0'}.$$

This result is of some interest, as showing that the electrical time-constant for a disk of *uniform* resistance ρ_0' must at all events be considerably less than 4·93 a/ρ_0'.[1]

The problem of induced currents is then discussed, more particularly in the case of a circular disk, of the kind indicated, rotating in any constant magnetic field. In view of the physical interest attaching to the question, it would be interesting to have a solution for the case of a *uniform* disk ; but in the absence of this, the solution for the more special kind of disk here considered may not be uninstructive.

In the most important types of induced currents, the magnetic potential $\bar{\Omega}$ due to the field $\propto xz$, so that the lines of force at the disk are normal to it, but the direction of the force is reversed as we cross the axis of z. The current-function relatively to axes displaced through the proper angle η in the direction of rotation, varies as

$$y\sqrt{\{1 - r^2/a^2\}}.$$

In the next type $\bar{\Omega} \propto z(x^2 - y^2)$, and the current-function, relatively to displaced axes as before, varies as $xy\sqrt{1 - r^2/a^2}$.

"Note to a Memoir on the Theory of Mathematical Form" (Phil. Trans. 1886, vol. clxxvii. p. 1). By A. B. Kempe, M.A., F.R.S.

The object of this note is to make some slight but important amendments of certain sections of the original memoir (viz. secs. 5, 7, 73 to 77, and 167), relating to the definition and use of what the author terms "aspects" of collections of things. An "aspect" of a collection of n things is that which is under consideration when to each individual thing of the collection we mentally affix a distinctive degree of prominence or other mark. These n marks may be regarded as interchangeable with each other, and we thus get $\underline{|n}$ aspects of the collection, of which some are undistinguishable from each other. If the interchanges corresponding to a complete system of undistinguishable aspects of the collection are given we know the "form" of the collection.

March 31.—"On Clausius's Characteristic Equation for Substances applied to Messrs. Ramsay and Young's Experiments on Alcohol." By Prof. Fitzgerald, Trinity College, Dublin.

This paper is an investigation of how far Clausius's equation

$$\frac{P}{R\tau} = \frac{1}{v - a} - \frac{1}{\Theta(v + \beta)^2}$$

represents accurately Messrs. Ramsay and Young's experimental results. It is shown that, considering the enormous range of values to be represented, it represents the results remarkably accurately, except that from the volume of the liquid, where alone the value of a is of much consequence, it follows that a is not constant, but is a function of both the temperature and pressure.

The paper contains a short discussion of the geometrical forms of the curves—a particular case of which is represented by this equation.

---

[1] Fell May 10, 1879, and contained embedded nodules of nickeliferous iron surrounded by silicates.

[1] I find by methods similar to those employed by Lord Rayleigh for the approximate determination of various acoustical constants, that the true value lies between $\pi a/\rho'$ and $2{\cdot}26\, a/\rho'$. For a disk of copper (ρ=1600 C.G.S.), whose radius is a decimetre and thickness a millimetre, the lower limit is 0·0014 sec. For disks of other dimensions the result will vary as the radius and the thickness conjointly.

It concludes with a hope that the velocity of sound in a substance near the critical point may be investigated, in order that we may know the two specific heats under these exceptional circumstances.

Physical Society, March 26.—Prof. Balfour Stewart, President, in the chair.—The following paper was read:—On the production, preparation, and properties of the finest fibres, by Mr. C. V. Boys. The inquiry into the production and properties of fibres was suggested by the experiments of Messrs. Gibson and Gregory on the tenacity of spun glass, described before the Society on February 12, and the necessity of using such fibres in experiments on which Prof. Rucker and the author are engaged. The various methods of producing organic fibres such as silk, cobweb, &c., and the mineral fibres, volcanic glass, slag wool, and spun glass, were referred to, and experiments shown in which masses of fibres of sealing-wax or Canada balsam were produced by electrifying the melted substance. In producing very fine glass fibres, the author finds it best to use very small quantities at high temperatures, and the velocity of separation should be as great as possible. The oxyhydrogen jet is used to attain the high temperature, and several methods of obtaining a great velocity have been devised. The best results obtained are given by a cross-bow and straw arrow, to the tail of which a thin rod of the substance to be drawn is cemented. Pine is used for the bow, because the ratio of its elasticity to its density (on which the velocity attainable depends) is great. The free end of the rod is held between the fingers, and when the middle part has been heated to the required temperature the string of the cross-bow is suddenly released, thus projecting the arrow with great velocity and drawing out a long fine fibre. By this means fibres of glass less than 1/10,000 of an inch in diameter can be made. The author has also experimented on many minerals, such as quartz, sapphire, ruby, garnet, feldspar, fluor-spar, augite, emerald, &c., with more or less success. Ruby, sapphire, and fluor-spar cannot well be drawn into fibres by this process, but quartz, augite, and feldspar give very satisfactory results. Garnet, when treated at low temperatures, yields fibres exhibiting the most beautiful colours. Some very interesting results have been obtained with quartz, from which fibres less than 1/100,000 of an inch in diameter have been obtained. It cannot be drawn directly from the crystal, but has to be slowly heated, fused, and cast in a thin rod, which rod is attached to the arrow as previously described. Quartz fibre exhibits remarkable properties, as it seems to be free from torsional fatigue, so evident in glass and metallic fibres, and on this account is most valuable for instruments requiring torsional control. The tenacity of such fibres is about fifty tons on the square inch. In the experiments on the fatigue of fibres great difficulty was experienced in obtaining a cement magnetically neutral, and sealing-wax was found the most suitable. An experiment was performed illustrating the fatigue of glass fibres under torsion, and diagrams exhibited showing that the effect of annealing them is to reduce the sub-permanent deformation to about 1/10 its original amount under similar conditions. Annealing quartz fibres does not improve their torsional properties, and renders them rotten. Besides the use of quartz for torsional measurements, the author believes that quartz thermometers would be free from the change of zero so annoying in glass ones. He exhibited an annealed glass spiral capable of weighing a millionth of a grain fairly accurately, and also a diffraction grating made by placing the fine fibres side by side in the threads of a fine screws. Gratings so made give banded spectra of white light. The author regretted that his paper was so incomplete, but thought the results already obtained would be of interest to the Society. Prof. W. G. Adams congratulated the author on his most interesting paper, and considered the results to be of great importance. He believed the banded spectra exhibited by the grating were probably due to internal reflection within the fibres. Mr. Cunyngham asked whether the glass mirror used in the torsional experiments was magnetic, to which the author replied that this was probable, but even this assumption did not explain all the peculiarities observed.—A paper by Prof. Pickering was postponed till the next meeting, on April 23.

Edinburgh

Scottish Meteorological Society, March 30.—Half-Yearly Meeting.—Mr. John Murray in the chair.—It was reported that four new stations had been recently added, viz., Aberfour, Oban, and Ailsa Craig and Oxcar Lighthouses; and an arrangement had been entered into with the Meteorological Council by which daily observations of temperature and rainfall are transmitted for the Weekly Weather Report issued by the Council for agricultural and sanitary purposes from the Society's stations at Lairg, Glencarron, Fort Augustus, Braemar, Ochtertyre, Marchmont, and Glenlee. Messrs. R. M. Smith, John Murray, and J. Y. Buchanan were re-elected members of the Council. The work of collecting and discussing the sea temperatures round the Scottish coast, for which a grant of 50*l*. has been obtained from the Government Grant Committee, has been transferred to Mr. H. N. Dickson. The report from the Council enters somewhat in detail into the physical and biological work carried on at the Scottish Marine Station. Six trips have been made since July by the *Medusa* in the Firth of Clyde and connected lochs, during which observations of sea temperatures were taken at all depths from the surface to the bottom, special attention being directed to the further investigation of the remarkable and unexpected distribution of temperature occurring in this part of the ocean at certain seasons, as disclosed during previous trips of the *Medusa*. Dredging was also vigorously prosecuted, and all the specimens obtained have been determined, their anatomy investigated, and the results prepared for publication by the staff of the Scottish Marine Station. This Station continues to be largely taken advantage of by biologists, for whom tables are provided in the laboratory free of charge, for prosecuting their zoological researches. As regards the Ben Nevis Observatory, it was reported that the subscriptions raised since the commencement of the present year for clearing off the debt and founding a low-level station of the first order at Fort William now amounted to 822*l*., thus bringing up the amount contributed by the public since the establishment of the Observatory in 1883 to nearly 8000*l*.—An address was then delivered by the Hon. Ralph Abercromby, at the request of the Council, on modern developments of cloud knowledge, with lime-light illustrations of clouds from all parts of the world. It was shown that clouds were everywhere the same, and that the different forms of clouds which he had exhibited from all regions of the globe could be seen in Scotland. A modification of the present classification of clouds which has been proposed by Prof. Hildebrandsson, of Upsala, and himself, was explained and illustrated. He then dealt successively with the structure of clouds and their height, the atmospheric conditions concerned in the formation of the different kinds of clouds, the remarkable results to which cloud-motions led as regards the nature of cyclones and anticyclones, the forecasting value of clouds, and finally the necessity of attending, in all efforts to interpret the indications of clouds, not merely to their forms, but also to their surroundings. In moving a vote of thanks to the lecturer, Prof. Chrystal took occasion to refer to the great beauty of the photographs shown by the lime-light, which were highly appreciated by a large and influential audience.

Paris

Academy of Sciences, April 4.—M. Janssen, President, in the chair.—Researches on certain phenomena connected with the aberration of light, by M. Fizeau. The paper deals chiefly with the nature of the phenomena that may be produced in the reflection of a pencil of light on the surface of a mirror, assuming this mirror to be endowed with a velocity comparable to that of light.—Stroboscopic method for comparing the duration of vibration of two diapasons, or that of the oscillation of two pendulums, by M. Lippmann. A description is given of a very accurate process of making these comparisons derived from the stroboscopic method.—On the central calm in cyclonic storms, by M. H. Faye. This central stillness is found to be present in all tropical cyclones, persisting even beyond the 50° latitude, but becoming modified according as the storm approaches the Pole without ever disappearing altogether.—On various effects of irritation in the throat, and especially on loss of sensibility and sudden death, by M. Brown-Séquard. Numerous experiments tend to show that the skin of the throat possesses, like the larynx, but to a less degree, the power of arresting sensibility; also that the larynx, the trachea, and also, perhaps, the cuticle covering them, possess the power of causing death under a mechanical irritation in the same way as the rachidian bulb.—On the seismic phenomena of February 1887, by M. Ch. V. Zenger. A parallelism is suggested between these disturbances and atmospheric, electric, and magnetic phenomena and volcanic eruptions so often occurring simultaneously.—Rectification of right, unicursal, circular cubics by means of the elliptical integrals, by M. G. de Longchamps. In supplement to his recent note, the author here establishes the important generalisation that all these cubics may be rectified by means of the elliptical integrals.—On the voltaic arc, by M. G. Maneuvrier. A new process is described, by means of which the voltaic arc may be excited without previous contact of the two electrodes.—Law of distribution of the rays and bands common to several spectra of bands, by M. Deslandres. Having already shown that the rays composing the same band may be divided into a series of identical rays, such that in each series the intervals between one ray and the following run pretty well in arithmetical progression, the author here extends this simple law of distribution to the bands of the same spectrum of bands, indicating an analogy with the law of succession of sounds in a solid body.—Fatal accidents in electric workshops, by M. A. d'Arsonval. Some remarks are presented on the causes of these accidents, on their physiological effects, and on the means of preventing them.—Quantitative analysis of vanadic acid, by M. A. Ditte. It is shown that by observing certain precautions the method indicated by Berzelius, based on the insolubility of the vanadate of ammonia in sal ammoniac may be applied to the analysis of vanadium in the form of vanadic acid with satisfactory results.—On some ammoniacal combinations of the sulphate and nitrate of cadmium, by M. G. André. Some details are given for the preparation of the ammoniacal sulphates and nitrates of cadmium, with indications of their possible relations to the corresponding salts of zinc and copper.—On the extraction and analysis of the vanadium occurring in rocks and mineral ores, by M. L. L'Hôte. The method here described involves two operations: the extraction of the vanadium in the form of vanadic solution, and its analysis by means of titrated liquors, or by weighing.—On the preparation of the propylamines and iso-amylamines, by M. H. Malbot. The observations recently made by the author on the isobutylamines are here extended to the amines derived from various alcohols.—On the power of multiplication of the ciliated Infusoria, by M. E. Maupas. This power is shown to depend on three factors: the quality and abundance of nourishment; temperature; and the biological adaptation of each species from the alimentary standpoint.—Results obtained by the preventive inoculation of the attenuated virus of yellow fever at Rio de Janeiro, by MM. Domingos Freire, Paul Gibier, and C. Rebourgeon. Of the 1675 cases terminating fatally between January 1885 and September 1886, only 8 had been vaccinated, and these at a time when the treatment was still imperfectly understood. In general, the mortality is now 1 per 1000 for the vaccinated, and 1 per 100 for all others.

BERLIN

Physiological Society, March 25.—Prof. du Bois-Reymond, President, in the chair.—Prof. Falk spoke on the influence of extremes of temperature on the colour of blood. In persons either burnt or frozen to death the *post-mortem* patches present a strikingly bright red colour. The speaker has found, as the result of an experimental investigation, that temperatures of 0° C., and below, lead to the colour of the blood becoming bright red by causing the oxygen of the air to be more readily fixed and more stably retained by the corpuscles than is the case at ordinary temperatures. If, however, the blood has stood exposed to the air until putrefactive changes have set in, in this case the action of cold no longer makes the blood brighter in colour. Other experiments have shown that in animals killed by low temperatures the blood is bright red, not only in the peripheral parts but also in the heart and great vessels. Also in human beings frozen to death the blood even in the heart is sometimes observed to be bright red, although in most cases only the blood of the peripheral parts presents this appearance; probably death has ensued from freezing only in cases presenting the first of these two appearances.—The President read a communication from Prof. Fredericq, of Louvain, on Traube-Hering curves. As is well known, a blood-pressure tracing recorded by a mercurial manometer, shows three distinct kinds of curves:—(1) Curves of the first order, which are caused by the systole of the heart. (2) Curves of the second order, which make their appearance at lengthy intervals and are synchronous with the respiratory movements: these curves represent the influence of the respiration on the blood-pressure. (3) Curves of the third order, which make their appearance at still longer intervals and were first described by Siegmund Meyer: these have usually been regarded as due to a rhythmic increase and diminution in the activity of the vaso-motor centre. The curves described by Traube and Hering have until now been regarded as belonging to the above-mentioned third order of curves. Prof. Fredericq, however, regards this as an incorrect view; he regards them as belonging to the second order, corresponding to and produced by the respiratory movements.—Dr. Wurster stated that he has treated the caseine-like substance (see NATURE, vol. xxxv. p. 455) obtained by the addition of hydrogen-peroxide to white of eggs with ammonia, and finds that a portion of this substance is thereby dissolved. Another portion, however, is converted into a ropy mass, which on being dried yields a horny substance, with a very marked affinity for colouring matters, and which exhibits nearly all the characteristics of horn. He has further found that these two bodies undergo no change by the action of nitrite of soda on the white of eggs. By the addition of lactic or acetic acid he has obtained a yellow precipitate which turned intensely red on exposure to the air: the same reagents applied to blood produced a black coloration.—Prof. Zuntz gave a short communication on the course of experiments which he has made in conjunction with Profs. Virchow and Senator on Cetti during his fast lasting over eleven days. The results of the investigation have not yet been completely put together, but will be communicated at an early sitting of the Physiological Society.

GOEBEL'S OUTLINES OF THE CLASSIFICATION OF PLANTS

Outlines of Classification and Special Morphology of Plants. By Dr. K. Goebel. A New Edition of Sachs's "Text-book of Botany," Book II. Authorised English Translation by Henry E. F. Garnsey, M.A. Revised by Prof. I. Bayley Balfour, M.A., M.D., F.R.S. (Oxford: Clarendon Press, 1887.)

ALL botanists who have been familiar, since 1882, with the original of this admirable work, will welcome the present translation, while it will be of even greater value to the large class of students who were unable to make use of the German edition. The full importance of Prof. Goebel's work will only be realised by those who have some acquaintance with the immense progress made in the morphology of plants since 1874, when the last German edition of Sachs's "Text-book" was published. Not a few of the most important of these discoveries are due to Goebel himself, and this fact, no doubt, partly explains the remarkable success with which he accomplished the difficult task of re-writing Sachs's Second Book. Goebel's work is, to all intents and purposes, a new one; but, at the same time, Sachs's own words have been incorporated in the new text in every case where the progress of the science did not actually demand a change.

Important additions to our knowledge have of course been made since the first appearance of this work in Germany. These have been duly recorded, in the English edition, by Prof. Balfour, who has wisely limited the additions to foot-notes. In one or two cases it might, perhaps, have been wished that these notes had been a little fuller.

It will not be without interest to enumerate some of the more striking differences between this work and the corresponding portion of Sachs's treatise. It must not be forgotten that Dr. Vines's revised edition of the latter work had already brought many of these points before English readers.

The same fourfold division of the vegetable kingdom which was adopted by Sachs is maintained here, though it is pointed out that a division into three (Thallophytes, Archegoniatæ, and Angiosperms) would be equally justified. The practical advantages of the former arrangement are obvious. In the classification of the Thallophytes we at once recognise a great advance. The artificial "sexual system," as it has been called, is quite given up, and an arrangement adopted which is based, as far as possible, on the entire life-cycle of the plants in question. Most teachers of botany will already have long abandoned the groups of "Protophyta, Zygosporeæ, Oosporeæ, and Carposporeæ," but it will be an immense gain to students to have a more natural system embodied in a text-book. In Goebel's system we have five main groups. Of these, the first two (Myxomycetes and Diatoms) are kept separate from the rest, on the ground of their uncertain relationships. Then we have the Schizophytes, including the Cyanophyceæ or blue-green Algæ on the one hand, and the Schizomycetes or Bacteria on the other. Then come the two main lines of the Algæ and the Fungi, which are thus again recognised as constituting natural classes, after the separation of the lower groups above mentioned.

The present arrangement is essentially that of De Bary, and no one will doubt that it approximates as nearly to a natural classification as our existing knowledge admits of. The fact that the conditions on which Sachs based his division have been repeatedly shown to vary among the most nearly related plants, is sufficient proof of the necessity for a return to less artificial views. It is to be regretted that no satisfactory place for the Diatoms has yet been found in classification. As regards the Myxomycetes, it will scarcely be doubted that they have no near relationship to any of the higher groups of plants. The fact that the fusion of the plasmodia is not accompanied by a union of their nuclei shows that this process cannot be regarded as a sexual one.

It will be observed that the Yeast-Fungi no longer appear side by side with the Bacteria, but are treated, in accordance with De Bary's views, as reduced Ascomycetes.

In the Algal series, attention may be called to the interesting section on the Volvocineæ, among which the transition from zygosporous to oosporous reproduction can be traced with special clearness. The discoveries relating to Acetabularia, Dasycladus, &c., show that a similar advance has taken place within the very distinct group of the Siphoneæ, while even among the simpler Protococcaceæ indications of an external differentiation between the sexual cells are not wanting. The account of the Phæophyceæ is of special interest from the same point of view, the series from Ectocarpus through Cutleria to Fucus showing the passage from simple conjugation of motile gametes to typical fertilisation of an oosphere by a spermatozoid.

The treatment of the red sea-weeds shows, on the whole, a great advance, though we anticipate still greater changes when the next edition comes to be written. We may venture to express a doubt as to the view here adopted, that the Bangiaceæ are simple forms of the Florideæ. Schmitz has already shown how slight are the grounds on which this arrangement is based. It seems to us probable that a relationship of the Bangiaceæ to the Ulvaceæ may again be recognised in the future, as has already been suggested by Mr. Bennett.

The account of the Characeæ is little modified from that in Sachs, but it will be noticed that they are here treated as oosporous Chlorophyceæ. The question of their systematic position will probably long remain insoluble, but there can be no doubt that they have little in common with any of the carposporous forms of Algæ.

Among the Fungi many changes will be found, of which only one or two can be referred to here. The gradual progress of apogamous degeneration among the Peronosporeæ and Saprolegnieæ, so important for the whole question of sexuality in Fungi, is fully described in the light of De Bary's researches.

Among other points, we may mention the advances in our knowledge of the Lichens, especially of their reproduction, and also the view here adopted, that the Basidiomycetes are wholly asexual forms, their so-called fruit representing a complex gonidiophore.

Leaving the Thallophytes, many signs of advance will be found in the description of the Muscineæ. Attention may especially be called to the very clear account now given of the embryology both of the Liverworts and of the true Mosses. In a future edition a fuller account of the vegetative anatomy of the latter class may perhaps be looked for.

In the group of the Vascular Cryptogams the changes have been very numerous. Goebel's view of the essential distinction between the forms in which the sporangium arises from a single cell, and those in which a whole group of cells takes part in its formation, gives the clue to the arrangement here followed. Indeed, there is no part of the book in which the author's own researches have given rise to more important results. The whole subject of the development of the sporangia, both among vascular cryptogams and flowering plants, is one which Goebel has especially made his own.

As regards other points, we may mention that the important subject of apogamy in Ferns is treated at length in the text, while the converse phenomenon of apospory, more recently investigated by Prof. Bower, is dealt with in an editorial note. The embryology of the whole group is treated much more completely than before, and illustrated by new figures. The brilliant discoveries of Treub in the Lycopodiaceæ are shortly recorded in a note, but his most recent work did not appear in time to be noticed.

Going on to the Gymnosperms, we find that the researches of Treub have here led to important advances in our knowledge of the Cycadeæ. The Coniferæ are treated very fully, and here it is more especially to the labours of Strasburger that the most important progress is due. To him are to be attributed most of the recent discoveries on the development of the macrosporangium and of the prothallus and embryo. It need scarcely be pointed out that these results, in conjunction with the investigations of the author himself, have demonstrated in every detail the homologies between Gymnosperms and Pteridophyta long ago detected by the genius of Hofmeister.

Before leaving the Coniferæ, attention must be called to an error which has, curiously enough, survived through several editions of Sachs's "Text-book," and through both the German and the English versions of the present work. At the middle of p. 337 it is stated that in Juniperus the lowest of the three cells derived from the oospore divides into four cells, each of which gives rise to a rudimentary embryo, so that four rudimentary embryos proceed from one archegonium. At the bottom of the same page we find the following sentence: "But *Picea vulgaris* agrees with *Juniperus*, inasmuch as the lowest of the three primary cells of the suspensor does not divide, but forms only one rudiment." Of these two contradictory statements the former is, of course, the correct one; in the sentence last quoted, *Thuja* should be read for Juniperus.

As regards the Angiosperms, the most considerable changes introduced relate to the development of the stamen on the one hand, and of the ovule and embryo-sac on the other. In the former case it is especially the work of Warming, in the latter that of Strasburger, to which our present knowledge of the facts is due. The treatment of all these subjects by the author of this book is singularly clear. The student will see how the homologies, which were so evident in the case of the Gymnosperms, can also be traced here up to a certain point, while he will also see exactly where our knowledge is still deficient.

The improved account of the embryology of Angiosperms may also be noticed, especially the interesting summary of Strasburger's investigations on polyembryony.

As regards the translation, both Mr. Garnsey and Prof. Balfour may be warmly congratulated on their success. Here and there a slight want of clearness may perhaps be noticed, but this is very rare, and scarcely any errors have been detected. One on p. 17 may, however, be pointed out. It is there stated that in the Myxomycetes "a plasmodium moves away from illuminated spots; if a stronger light is thrown directly upon these spots, a number of plasmodia collect in them." This does not express the fact as stated in the original, which is that, if *the plasmodia* be directly exposed to strong light, they form larger conglomerations. Again, at the top of p. 97, the phrase "*ins Freie*" should scarcely have been translated "into the air," in speaking of a submerged aquatic plant.

The explanation of terms at the end of the book will be of the greatest possible value not only to students but to botanists. We may hope that it will materially contribute to introduce order into the chaos of our terminology. We are glad to see the good old term *spermatozoid* replacing the inaccurate *antherozoid*, and we could wish that ovum could constantly be used for oosphere. Where clear homologies with the animal kingdom can be traced, it seems a distinct loss to ignore them.

On the other hand, we cannot feel satisfied with the word "sporophyte" for the asexual generation in the higher plants. "Sporophyte" is the correlative of "spermaphyte," and has actually been used by Luerssen and others in the sense of a Cryptogam, as distinguished from the seed-bearing Phanerogam. We should have thought that the older terms "sporophore" and "oophore" would answer every purpose.

In conclusion, we can only say that the appearance of this book marks the most important addition to our morphological literature since 1875. D. H. S.

MINERAL PHYSIOLOGY AND PHYSIOGRAPHY

Mineral Physiology and Physiography. A Second Series of Chemical and Geological Essays, with a General Introduction. By Thomas Sterry Hunt, M.A., LL.D. Pp. 638. (Boston: Samuel E. Cassino, 1886.)

THIS work, as its sub-title implies, is a continuation of the series of essays first published by Dr. Sterry Hunt in 1874, of which a second and revised edition appeared in 1878. The essays which make up the present volume have with one exception, that on "The Genetic History of Crystalline Rocks," already appeared in various scientific journals.

The principal title of the work is explained and justified by its author in the two first essays. Dr. Sterry Hunt advocates a return to the older and wider meaning of the term "physiology" as it was employed two centuries ago; he maintains that all the natural sciences fall into two great divisions, the descriptive or physiographical, and the philosophical or physiological. It seems scarcely necessary to point out that the term physiology is now so universally restricted to the study of the actions of organised beings that any attempt to make it include physics and chemistry, with a large part of geology and astronomy, as the author proposes, can scarcely be expected to meet with much success. In scientific terminology a struggle for existence is continually going on, and it is hopeless to fight against the results of selection: to endeavour at the present day to revive the older and wider meaning of the term "physiology," and to use it as a synonym for "natural philosophy" side by side with the modern and more restricted sense, must almost infallibly lead to confusion. Still more hopeless would it be to try and abolish the use of the term in its present accepted sense.

In the third essay, on "The Chemical and Geological Relations of the Atmosphere," Dr. Sterry Hunt states and defends his well-known speculation concerning the replacement of the carbonic dioxide which is being continually removed from the atmosphere by the processes of kaolinisation and of coal-formation. Rejecting the too obvious suggestion advanced by Stanislas Meunier and others, that the equivalent of the carbonic dioxide abstracted from the atmosphere by the processes in question may be returned to it from subterranean sources, the author insists that such supplies can only come from outside the earth's atmosphere, and must be cosmical in their origin. The fourth essay, following up some of the ideas hinted at in the third, deals with "Celestial Chemistry from the Time of Newton," and is principally occupied with a discussion of the nature of interstellary matter.

The two essays dealing with "The Origin of Crystalline Rocks" and "The Genetic History of the Crystalline Rocks" are devoted to a destructive criticism of various theories which have been propounded to account for the origin of the crystalline schists and gneisses, and the attempt to supply a new one. As is well known, Dr. Sterry Hunt is one of those who maintain that all rocks of this class are necessarily of Archæan age; unlike some of his contemporaries who share the same views, however, he does not shrink from what he believes to be the logical conclusion from these premises, and maintains that the formation of such rocks must result from actions of a very different kind from any now going on upon the globe. According to Dr. Sterry Hunt's idea, which he calls the "crenitic hypothesis," "the crystalline stratiform rocks, as well as many erupted rocks, are supposed to be derived from a primary superficial layer, regarded as the last portion of the globe solidified in cooling from a state of igneous fluidity." After the wonderful speculative flights of these two essays, Dr. Sterry Hunt returns to the ground of sober scientific thought in several essays where ordinary chemists and geologists will not find themselves altogether out of their depth.

The solid contributions made to mineralogical science by the author of these essays may perhaps warrant an attempt on his part to deal with the difficult and involved question of mineralogical classification. This subject he has treated in his essay, "A Natural System of Mineralogy," an elaboration of which is promised in a treatise on mineralogy now in preparation. Dr. Sterry Hunt adopts, as might be anticipated, a purely chemical classification; but his results, which differ in many important particulars from those both of Rammelsberg and Tschermak, do not attract us by their simplicity, and seem perhaps needlessly obscured by the adoption of a very cumbrous terminology.

The essay on "The Geological History of Serpentines" is one in which all the author's peculiar originality and boldness are displayed in their highest perfection. That in the face of the results obtained by the study of rocks with the microscope, anyone could be found to maintain at the present day the *aqueous origin* of many, if not all, serpentines, may seem startling to those who have not read the author's previous writings on the subject. The dexterous gliding over difficult and dangerous places, and the elaborate "figure-cutting" on a few strips of apparently solid ice, constitute one of the most remarkable displays of courage and skill ever exhibited—even by the great mental athlete of Canada himself!

The "Taconic" rocks have formed in North America the battle-ground for two rival schools of geological thought, exactly comparable to that afforded by the Alps to European geologists, and the Scottish Highlands to those of Britain. In the ninth and eleventh essays of the present volume, Dr. Sterry Hunt maintains and stoutly defends his well-known views concerning the origin and succession of the Archæan rocks. For him the most highly foliated schists and gneisses exhibit a stratification clearly due to some kind of sedimentation; in the mineralogical constitution of these rocks he finds evidences of geological age more trustworthy even than those of the organic remains in the later aqueous deposits, and relying implicitly upon this kind of evidence, he has evolved a universal classification for the Archæan deposits which he can apply equally to the rocks of Southern Europe and of British North America. At some of these results persons of less robust faith in Dr. Sterry Hunt's methods can only give way to "admiration," as, for example, when igneous rocks which have been demonstrated to be intrusive in Secondary deposits, are boldly claimed, on account of their mineral characters, as members of some Archæan "system"!

Throughout the present volume, as in the former one, Dr. Sterry Hunt keeps prominently in view his claims to priority, and jealously defends the originality of many of the ideas he puts forward. We cannot but think ourselves that the claim to originality is one which he need take the smallest care to insist upon. If no name had appeared upon the title-page of this remarkable work, every chemist and geologist glancing at its pages would have felt assured that its author could be no other than Dr. Sterry Hunt.

OUR BOOK SHELF

Through the Fields with Linnæus. By Mrs. Florence Caddy. Two Vols. (London: Longmans, Green, and Co., 1887.)

THIS enthusiastic book is the fruit of the author's visit to the land of Linnæus, and her journeys in his track. Its purpose is to tell the story of the life and labours of Linnæus with the local colour so far as it may be restored from contemporary and other records, and from the author's own experiences of travel. We find Linnæus here presented to us sometimes, as in the story of his early struggles while a student at Upsala, and again at the period of his courtship and his absence from the object of his affections, with the air of the hero of a romance rather than the subject of sober biography. It was to be expected that such periods in his life-history would properly take forcible hold of the sympathies of a lady biographer. It may be said at once that the author has carefully consulted the proper authorities—Stoever, Pulteney, Smith, Jackson, &c., and duly acknowledged her indebtedness to them; and occasionally, with more jubilation than mere complacency, her disregard for them when they fail by disagreement among themselves, or otherwise, to satisfy her. One can hardly say fairer than that. The first impression of the book is unfavourable; in fact, it is felt that one cannot take it seriously. That it is not meant to be so taken altogether is manifest from such statements as that "by Hök rather than by Krök Carl's name was enrolled," &c. Apart from this kind of thing, however, there is often a temptation to smile at the wrong places. The author's observations on men and things in general are frequent and fearless. For example, in discussing an architectural matter she wonders at "the usually perceptive Fergusson" not recognising the significance of a feature well known to ordinary writers on Swedish architecture. Doubtless Mr. Fergusson would have valued this gentle way of describing him, so unlike the manner of those "cock-a-hoop and overbearing young scientific men" whom the author prophesies will be "charming at forty." There is a superabundance too of quotations in the book beyond the legitimate quotations from Linnæus himself and writers of his life. Indeed, to put it in the fashion of that biographer of Linnæus whom she calls "dear old Stoever," she can rarely keep her course clear of the Scylla of her own wisdom and the Charybdis of miscellaneous quotations from Carlyle and a great variety of other writers.

The ancestors of Linnæus, his life from boyhood and school-days, throughout his University career, are discussed with picturesque descriptions of the land and the people. We then come to his *début* in the treatise on the sexes of plants, in answer to Wahlin's "Nuptiæ Arborum Dissertatio." "This," we are told, "was a blooming new idea in the summer of 1730." He is then followed throughout his travels in Lapland, Dalecarlia, his fruitful visits to Holland, England, and France, his return to Sweden and career at home, including his subsequent journeys—to the end. The following passage will give a fair illustration of the style of the more extravagant passages in the book:—

"Linnæus broke down: he dropped like the begonia at the last—the flower that had always interested him so much, with its male and female flowers so graceful and so differing. The common begonia, that most interesting and elegant of plants, is jointed all the way up, and as it withers the joints become separated and in shape like the bones of the human limbs; they drop apart, and fall like dry bones upon the ground. This family is a botanical study in itself. 'Many begonias are remarkable for the production of adventitious buds,'" &c.

In spite of this amazing style it must be owned that apart from such small matters as spelling Linnean, in the name of the Society, "Linnæan," the book is wonderfully correct in the main features of the life of Linnæus, and once the reader is accustomed to absurdities such as we have noted, it becomes a readable narrative. The worst of it is that one is hurried off to somewhere between China and Peru for an illustration of some sober fact, and this without sufficient warning to the unwary reader.

Sur une nouvelle Méthode de faire des Mesures absolues de la Chaleur rayonnante. Par Knut Angström. (Upsal: Berling, 1886.)

In this quarto pamphlet of seventeen pages (with a plate) the author claims to give a simple method for determining the absolute measure of radiant heat, and describes a self-registering apparatus which gives the intensity of solar radiation at any instant, as also the total heat received by the absorbing surface in a given time. Two circular copper disks are alternately exposed to the source of heat and screened from it, and a thermo-electric couple and galvanometer give the differences of their temperature. The method consists in finding accurately the average *time* for the *temperature-difference* of the two plates to be a given (small) amount, positive and negative in turns. By the aid of Newton's law of cooling, which is applicable in this case, the author proves that the intensity of the radiation is proportional to the temperature-difference directly, and the time inversely, and that it is quite independent of the constant of cooling. To verify the last conclusion, the author measured with an instrument of this kind the radiation of a constant source of heat under varying conditions of cooling, and he found that the influence of cooling was completely eliminated.

In the construction of the self-registering actinometer founded on this principle, the absorbing surfaces are those of a differential thermometer, and the temperature-differences are marked by the movement of a thread of mercury in the communicating glass tube. When the thread has moved a certain distance, corresponding to a known temperature-difference in the two bulbs, an electric circuit is completed, and an electro-magnet turns the instrument through 180°, thus reversing the positions of the screened and unscreened bulbs. By the usual clock-driven pencil and revolving cylinder, a curve is drawn of which the abscissa is proportional to the time, and the ordinate to the number of turns which the instrument has made in the time. It is then shown that at any instant the intensity of the radiation is proportional to the tangent of the angle which the curve makes with the axis of abscissæ, and that the total heat received in a given time is proportional to the difference of the ordinates corresponding to the beginning and end of the time. The constants by which these variables are to be multiplied must be found by comparison with an absolute instrument like that already mentioned, and the necessity for this comparison may prove an obstacle to the general use of the instrument. Notwithstanding this drawback, the author claims for his invention that it gives results in accordance with those of the absolute instrument, and that it works as satisfactorily on stormy days as on calm ones. There is no doubt that the instrument is deserving of a fair trial, and a comparison of the results obtained from it and from some other recent forms of actinometer, would be of great value.

The paper is carefully written and printed, and we have noticed only two unimportant slips: one on p. 9, last line but one, where 40·0 should be 41·0; and another on p. 16, line 9, where *plus* should be *moins*.

T. H. C.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.*]

Vitality and its Definition

While warmly congratulating Prof. Judd upon the ability with which he has brought "out into clear relief the analogies between the science dealing with the mineral kingdom and those concerned with the animal and vegetable kingdoms," I cannot but think he has a little understated the difference between organic and inorganic matter. As this has arisen from a misconception of Mr. Spencer's definition of life—a misconception which has previously come before my notice in cases where other minds have looked at this same question—I venture to think you will allow me a few lines to show from what it arises, in the hope of expounding a subject which, popularly understood, must undoubtedly appear a little complex.

If, instead of taking the "concrete equivalent" of the definition, which the Professor has taken, though it is only used in the original "for our present purpose," we take "the broadest and most complete definition of life," . . . "*the continuous adjustment of internal relations to external relations*" ("Principles of Biology," vol. i. p. 80), we shall find that the changes undergone by minerals, even the physiological changes, will not obviously come within it; for it appears to me that, in the illustrations named in last week's NATURE, the minerals only display a continuous adjustment of internal *changes* to external *changes*. A change in the incident forces produces a change in the internal molecular arrangement of the mineral; a further change in the forces is *followed* by a further molecular, or molar, rearrangement in the mineral, and so on. There is no *anticipatory*, or *induced, change*—this is the point—in the mineral, which will correspond with the change which usually is connected with, and is sequent upon, the first environmental change, as is the case with living organisms. A quotation from the "Principles of Biology" (vol. i. p. 79) in conclusion will, I hope, now make my meaning clear. "If a creature's rate of assimilation is increased in consequence of a decrease of temperature in the environment; it is that the *relation* between the food consumed and heat produced, is so re-adjusted by multiplying both its members, that the altered *relation* in the surrounding medium between the quantity of heat absorbed from, and radiated to, bodies of a given temperature, is counterbalanced. If a sound or a scent wafted to it on the breeze, prompts the stag to dart away from the deer-stalker; it is that there exists in its neighbourhood a *relation* between a certain sensible property and certain actions dangerous to the stag, while in its organism there exists an adapted *relation* between the impression this sensible property produces, and the actions by which danger is escaped." The importance attaching to the word *relation* in this quotation has led me to emphasise it by italics.

Churchfield, Edgbaston   F. HOWARD COLLINS

Oldhamia

PROF. SOLLAS's ingenious suggestion as to the origin of *Oldhamia* (NATURE, p. 515; Proc. R.D.S. p. 355) undoubtedly deserves very careful consideration; but it appears to me to leave some serious difficulties unexplained. For instance, the following occur to me after reading his paper and after examining two very fine specimens—one of *O. antiqua*, the other of *O. radiata*—recently placed in my hands by Mr. R. H. Scott, F.R.S.:—(1) The "puckerings," which are supposed to simulate the organism, are more definite in their boundaries than is usually the case with the ridgy or wavy "rucking up" which often occurs in phyllites as a first stage in the production of *Ausweichungsclivage*. (2) While I can trace down into the mass of the slate a certain puckering, I am at present unable to connect it with the *Oldhamia* visible on the upper surface. (3) As Prof. Sollas himself remarks, it is difficult to account for the peculiar branching form of *Oldhamia*. As it happens, during the last two or three years I have seen many examples of puckered phyllites, but never met with anything like *Oldhamia*. This difficulty in the case of *O. antiqua* seems to me almost insuperable. (4) In some cases I can detect two sets of markings crossing one another, so that the surface of the stone shows a reticulate structure, one set of lines being less definite than the other. This looks very much as if one branch of an organism were lying on the top of another; but I cannot account for it by mechanical movements alone. (5) The constancy of character in the markings is also a difficulty. One would expect every stage of development from the least to the most imitative. Now, though the *Oldhamia* is often indistinct, it certainly seems to me more like bad preservation than imperfect development of a structure.

Of course I do not in the least question the accuracy of the observations made by Mr. Teall and Prof. Sollas on the structure of the Bray Head rock; I only doubt whether the relation of this to *Oldhamia* can be regarded as proved. However, I am having some slides prepared from the above-named specimens, and hope that they may help in solving my difficulties.

23 Denning Road, N.W., April 5   T. G. BONNEY

Disappearance of Bishop's Ring in Colorado

THE reddish ring about the sun first distinctly appeared here (at the base of Pike's Peak) on November 22, 1883. For several days before that date, a faint discoloration of the region about the sun had attracted my attention. This gradually grew more intense, and, on the day mentioned, became unmistakable. The subsequent history of Bishop's ring as seen at this place is, in brief, as follows:—

The colour was most intense during the winter of 1883–84, and diminished in brightness from that time until its disappearance. At first it was visible almost all the time. Later, it appeared only at the time of cold storms, which were accompanied by great vertical movement of the air, or when, for any reason, the clouds reached to a great height. It was, on the average, brighter during the winters than in the summers; also, it was brighter when the sun was near the horizon. Many times in cold weather there has been not a trace of the ring, although the air was so clear that peaks a hundred miles distant were distinctly visible from the heights behind this city. At other times the ring has been very bright when the air was so hazy that the mountains only ten miles away were hardly visible. During the later months of 1885 it was invisible most of the time, but suddenly flamed out in wonderful intensity at the time of the great norther of January 9–11, 1886. Then for about two months it frequently appeared in the morning, or towards evening. During the warm months of 1886 it was not seen. On October 15 it appeared distinctly. About a week later it appeared very faintly a few times, and since then I have not been able to see a trace of it. My observations have been made at elevations of from 6000 to about 13,000 feet, and there was but little apparent difference in intensity at the different elevations. It is well known that the atmosphere here is, in general, very dry and transparent.

The diffraction-ring was often more coppery, almost rosy, in tint at the time of the northers, and in the thickening haze in the upper air preparatory to hailstorms. The great intensity of the colour at such times, and its peculiar tint, and that, too, irrespective of the amount of haze in the lower atmosphere, makes it probable that the ring was in part due to diffraction on ice-particles. If so, the ice-particles may themselves have been due to precipitation on dust-particles. The fact that no diffraction-ring has been seen around the sun during the past winter is not conclusive, for we have had no great northers, the season being unusually mild. But the disappearance of Bishop's ring for so long a time makes it certain that, even if there can be a circumsolar glow due to diffraction on ice-particles, yet the proper conditions for such a ring are realised only rarely, except when there is a great amount of volcanic dust in the air.

Iridescent Clouds

SEVERAL brilliant displays of iridescent clouds have appeared here during the past winter. One, on January 19, lasted for more than two hours during a "Chinook" wind. A mass of closely-connected cirro-cumulus clouds formed at a great elevation directly over the eastern base of the Rocky Mountains, and thence extended eastward as far as the eye could reach. The western sky was clear. As the clouds drifted slowly eastward, new clouds formed along their western border. The western limit of the clouds was for several hours nearly stationary, then slowly advanced westward opposite the direction of cloud-motion. Along the western border of the clouds were many projecting tongues of cloud. At one time I counted seven complete spectra at the thinner parts of the clouds—all showing bands of red, green, and violet. There were also about twenty-five spectra showing only one or two of the colours. The larger of these iridescent spots were about 10° in diameter, and they varied in distance from 5° to more than 45° from the sun. Their tints were intensely brilliant. There were also great numbers of minute iridescent spots where the colours were in great confusion—a phenomenon which is very common here. They sometimes are so numerous as to simulate Bishop's ring.

A Claim of Priority

IN connexion with the letter of M. Ventosa headed as above in your issue of March 31 (p. 513), I should be glad if you would let me refer to a note which was appended to my paper on "Continuous Calculating Machines," in the Philosophical Transactions of the Royal Society, part ii., 1885.

This note, whilst giving due priority to M. Ventosa in the matter of *one* of the two features of the sphere and roller integrator, described in the above paper, a feature at which I need scarcely say I arrived quite independently, points to the fact that this forms but a part of the integrator in question. When combined with the other portion, that integrator is a calculating machine in the widest sense of the term. I have shown that in addition to giving the value of

$$\int y dx,$$

where y is any linear function of x, other varieties of the mechanism obtain the value of such expressions as

$$\int F_1(x) F_2(x) \ldots F_n(x) dx,$$

and

$$\int\int \phi(x, y) dy dx,$$

and also by a converse process give approximately the value at any instant of R where

$$R = \frac{dy}{dx}.$$

I had not before to day seen the paper of Mr. F. J. Smith in the *Phil. Mag.* (August 1886), referred to by M. Ventosa. On pp. 381 and 382 of my paper above alluded to will be found a description of an integrator which is practically identical with that of Mr. Smith, as I have no doubt he will admit when he reads that description. With that integrator *hollow* brass balls were employed for the very purpose suggested by Mr. Smith. The instrument was, however, abandoned in favour of more convenient forms, one of which was actually employed by that gentleman upon his "ergometer" at the Inventions Exhibition, together with some very ingenious integrators of his own design. There is, I would say, one point of difference between the integrator described by Mr. Smith, and that by myself. The movable arm in the former appears to be guided by a pin in a straight slot. Now in the "sine" form, of which this integrator is an example, this pin should move in the arc of a circle, and it would be interesting to know if approximately correct results have been obtained with what is in some respects a more convenient practical device.

The Vitality of Mummy Seeds

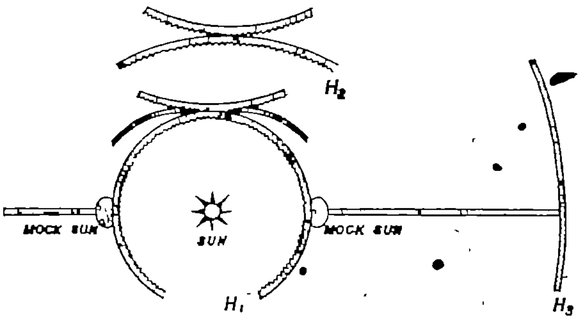
I READ with much surprise in NATURE of March 31 (in Prof. Judd's defence of his statement as to the longevity of seeds) that "competent botanists have cited the case of the germination of seeds taken from ancient Egyptian tombs as authentic." Many experiments have been made as to the length of time seeds may retain their power of germinating, by Robert Brown, Henslow, and others, with interesting results as to the longevity of some; but my impression is, and I venture to make it public, that competent botanists have universally condemned as utterly worthless the evidence given in support of alleged instances of the germination of mummy seeds. No scientifically responsible person has, so far as I am aware, put the fact on record. In these circumstances, therefore, the results of the successful experiments referred to farther on by Prof. Judd as having recently been made, possess the greatest interest, and botanists will look forward eagerly to the details which it is to be hoped will soon be made public. Hitherto the fruitful source of error has been the deception at the outset of the credulous experimenter by the Arab. In fact, the mummy wheat of one well-known traveller grew up in the form of *oats*—a plant not cultivated by the ancient Egyptians, but now grown in the land they inhabited—though this did not shake his faith in the genuine source of his supply. In the present case, however, the statement made in faith by so high an authority as Prof. Judd leads us to anticipate that the undertaking has been hedged in with all the safeguards demanded by a pure cultivation of undoubtedly genuine material.

GEORGE MURRAY

7 Onslow Place, South Kensington, S.W., April 5

Solar Halos

IN the forenoon of March 6 the sun was surrounded by a series of halos of the form shown in the diagram. The side of each arc, marked with a wavy or saw-toothed outline, was red, and the opposite edge blue; but no colour at all was visible in the horizontal belt nor in the farthest-out halo (H$_3$). This sketch shows the appearance at about 9 a.m.; as the sun rose higher, the horizontal belt got a curve upwards at each side—*i.e.* it continued to be parallel to the horizon—and was prolonged inside H$_1$ till it almost touched the sun. The two mock-suns were distinctly on the outside of H$_1$, and were coloured red next the sun, and blue outside, their reds about coinciding with the blue of H$_1$. The following are some of the measurements.—



Sun to western mock-sun	23 46
,, eastern ,, ...	23 12
,, H$_3$ (two measurements)...	79 56 81 23

The halo H$_3$ has, I believe, been very seldom seen, and there are only three estimates of its radius on record: two of these make it 90°, and the third makes it 85° to 90°. It will be seen that our measurements—both about 81°—are considerably less than any of the former ones.

On the Character of the Beds of Chert in the Carboniferous Limestone of Yorkshire

IT may be of interest to geologists to know that I have lately ascertained that the beds of chert which occur in the limestones of the Yoredale series of Yorkshire are distinctly of organic origin, and that, in fact, they are composed of the heterogeneously-mingled spicules of disintegrated siliceous sponges. The beds vary from 3 inches to 18 feet in thickness, and the limestones in which they are interbedded are nearly exclusively composed of the broken-up remains of crinoids, thus showing a well-marked alternation of periods in which sponges and crinoids succeeded each other. The spicules can only be studied in thin microscopic sections of the rock; in some cases they are very perfectly preserved and their axial canals are clearly shown; in other examples only very faint outlines can be made out. They appear to belong for the most part to the same group of Hexactinellid sponges as the recent genus *Hyalonema*, but Monactinellid spicules, like those of the existing genus *Reniera*, are also very numerous in some of the beds. Such an enormous accumulation of the debris of siliceous sponges proves that these organisms were as abundant in the Carboniferous as in the Cretaceous seas.

The beds of chert referred to are exposed near Harrogate, and at Richmond, Yorkshire, and they are remarkably developed at Arkendale, about fourteen miles above Richmond. I am indebted to Mr. J. G. Goodchild, of the Geological Survey, for directing my attention to this last-named locality. Owing to their resistant character, fragments of the beds are also widely distributed in the boulder-clays to the south of their outcrops, and I have met with them in these clays near York.

It has been known for some time that the remains of siliceous sponges are of common occurrence in the Carboniferous chert beds of Ayrshire and of certain parts of Ireland, but they do not appear to have been noticed hitherto in the corresponding beds of Yorkshire. I hope shortly to give a more detailed description of their principal characters.

GEORGE J. HINDE

Croydon, April 2

The Zirconia Oxy-hydrogen Light

I HAVE been interested in the brief note you gave upon Prof. Linnemann's zirconia light, and as I have for several years been endeavouring to obtain the alleged advantages of this earth as a luminant, and with very different comparative results, if you will allow me briefly to state these, it may possibly be of service. Zirconia has been stated by Du Motay to be the "most luminous" as well as most refractory of earths, and if it indeed be so, its advantages would be very great. I have made many fruitless attempts to procure one of Du Motay's own pencils as prepared and sold many years ago, but none seem now obtainable; if any reader possesses, and can lend me, one for trial (all the better if he can share in or witness it), I shall be exceedingly obliged, in the interests of improved optical projection.

With the assistance of Mr. Chadwick, of Manchester, Mr. H. G. Madan, of Eton College, and a third gentleman, of Leeds, my own experiments have been made with small cylinders about 9 millimetres diameter, compressed from three different samples of zirconia. The incandescent surface was the flat end of such a cylinder.

The first sample was sold as "pure" by Hopkin and Williams, and many cylinders were tried of it. It was very largely contaminated with soda, which might in time have volatilised; but a more hopeless impurity was the large quantity of silica, which quickly fused into a thick yellow glaze. The light was most inferior, but the reddish tinge presently noticed was *not* conspicuous in this sample, which was worthless as an illuminant.

The second sample was prepared by my Leeds colleague, largely by blow-pipe processes. It stood the flame much better, and contained far less soda, which rapidly lessened under the flame. It contained, however, considerable silica, which could be observed through dark glasses to seethe and melt into ridges. When this took place, the light rapidly diminished, and was never near that of a lime cylinder, though at one time respectable. Also, fissures appeared in the face. But the peculiar physical properties of the earth were conspicuous, and chiefly its extraordinary *non-conducting* power. With a powerful jet (capable of yielding 700 candle-power on a lime cylinder) playing upon the small surface described, the full incandescence barely reached the edge of the disk, and the bright portion only extended about 2½ millimetres up the cylinder, bounded by a definite line. At this line a crack all round began to appear, which gradually deepened, until at length the incandescent layer separated and fell off. The glow was of a most pronounced *reddish* character.

The third sample was procured by Mr. Madan from Herr Schuchardt, of Gorlitz; it is stated to be prepared "especially" for the oxy-hydrogen light, and is sold at the rate of 18 marks for 10 grammes, of which about half is required to form a cylinder. This sample shrank enormously when heated, both in powder and when first compressed—showing that it was very largely hydrated—and had to be re-crushed and compressed again before anything could be done with it. It was much more free from silica, and half an hour of a powerful jet only produced a slight glaze or polish on the face. The *reddish* glow was very prominent in it also. The most serious fault, or difficulty, was that the circular crack formed and deepened much more rapidly than in the preceding, and the layer separated in less than half an hour. I fear this unequal shrinkage and its effects will alone be a great obstacle, unless—which I much regret we did not test experimentally—the thin layer itself, as detached, should prove sufficient, held in a platinum loop. Possibly it might crack no further.

But the light was again *poor* compared with a good lime. Mr. Madan had the plug crushed and re-made, and tested the light photometrically in his own laboratory at Eton. Compared with a good quarry lime, the zirconia taken as unity was only 1 : 2·88, with the same jet. That is a very startling difference. It is true that the incandescent surfaces are probably in about the same proportion, so that the brilliancy *per unit of surface* may be about the same. But then the incandescent surface of the zirconia cannot be increased, owing to the non-conducting properties already alluded to; so that the fact remains, so far as illumination is concerned, that we can only get with zirconia, or with such samples as I was able to obtain, about *one-third* of the light we can get from a good lime.

This result is so different from that stated by Prof. Linnemann, and years ago by Du Motay, that some explanation seems necessary. I think it lies in the fact that Continental operators do not use nearly such powerful jets as are often used in England, where we obtain 600 to 700 candle-power. Several Continental jets have come into my hands, none of which would give a good light, as a first-class "magic-lantern" lecturer understands it, *i.e.* sufficient to illuminate a disk 25 feet in diameter. Prof. Linnemann's own jet, of which I have seen the drawings, though it has the useful property of condensing the heat into a very small spot, is only a form of the "blow-through," as usually called; and when he remarks upon the "unsteadiness" of the mixing jet, he shows that he is not practically acquainted with it in a good form. Again, I was given by Mr. W. G. Lettsom some time ago a sample of an "improved" composition sold in Germany instead of limes, and stated to be "much better" for oxy-hydrogen purposes; my jets simply burnt holes clean through it (a prism of about 18 mm. diameter) in less than a minute. Now it is noticeable that with a blow-through jet, of about 200 candle-power, the zirconia does compare much more favourably, and is about as bright as the lime.

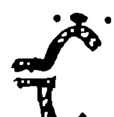
I write this, however, with a last hope of getting "more light" on the subject. If we could only get the whole light of a good lime-cylinder into the small disk (which is all that can be heated) of zirconia, the advantage would be very great: the parallel or other beam from the lantern from such a radiant is *as sharp* as from an arc light, and every Professor knows what that means. 700 candle-power without trouble—who does not long for it? It will be observed that each of the three samples described behaved differently, and it is in this fact lies my chief hope of any success yet; otherwise it is the decided opinion of all who have shared in these experiments, that the vaunted zirconia light is a sheer delusion. If any reader of these columns knows of purer samples to be procured commercially (I know Draper's process, but am no practical chemist, and have neither time nor means to prepare samples myself); or can tell me if the peculiar *red glow* noticed is characteristic of the earth itself or of some impurity; or has tested lanthana or any other of the more refractory earths; or can in any way assist me in what is, in its way, a matter of some importance to the science lecture-room, I shall feel much obliged for any communication from him, either here, or to LEWIS WRIGHT

7 Beaumont Road, Hornsey Rise, N.

The Production of Newton's Rings by Plane Soap-Films

LORD RAYLEIGH, in his recent lecture at the Royal Institution on "The Colours of Thin Plates," introduced Sir D. Brewster's experiment, in which circular rings instead of the usual straight bands are produced in a vertical soap-film by causing a jet of air to impinge very obliquely upon the film near its edge. The particles are thus thrown into a vortex-motion, and the centrifugal tendency causes the film to become thinner at the centre than at the edge, so as to produce very fair rings of colour.

Perhaps it may be worth mentioning that the same effect may be produced with greater regularity and less risk to the film, by giving the ring to which it is attached a rapid movement of rotation in its own plane. A shallow brass cup, about 8 or 9 cm. in diameter, the edge of which is turned inwards and rounded so as to give it the following section, is mounted on a horizontal spindle so that it can be turned rapidly in a vertical plane (any ordinary smooth-running multiplying-wheel arrangement will answer, but a small electromotor is by far the most convenient). The edge of the cup is just dipped below the surface of the soap-solution, and then the socket at the back is fitted on the spindle and rotation commenced. At first the straight horizontal bands of colour maintain their form and position, for the reason which Lord Rayleigh well explained; but, as the speed increases, the adhesion of the film to the edge of the cup, and the cohesion of its particles, cause it to take up gradually the motion of the cup; and, as the mass accumulates at the circumference, very perfect circular rings are formed, which can be projected with brilliancy on a screen by the lime-light. H. G. MADAN



Eton College

Barnard's Second Comet

THERE would appear to be some danger that the observation of the above comet may be relinquished rather prematurely, as it is still sufficiently bright for observation when viewed with our larger telescopes; and, as far as I am aware, there are no published ephemerides later than March 27. To remedy this want, I subjoin places calculated from the elements of Dr. Palisa for Greenwich mean midnight for the period during which the moon will be absent.

JOHN I. PLUMMER

Orwell Park Observatory, April 11

Sunspots

IN the summary in regard to solar activity in 1886, published in NATURE for March 10, p. 445, it is stated that, during the period from October 31 to December 12, "on six days only out of the forty-two could there be discovered on the sun any trace even of a spot, and on those days only one tiny spot could be seen." As observed in this locality, there were formed, in the midst of the faculæ which came into view on November 14, one spot on November 15 and two spots on November 16; all having disappeared on November 18, when observation again became possible. On December 8 the first of a group of spots which made a complete transit across the sun's surface appeared. On December 9 this group consisted of three spots, which persisted until the 13th at least, gradually increasing in size. A period of sunspot minimum is best adapted in certain regards to the study of the relations of solar outbursts to magnetic and auroral phenomena; hence precision at such times, in reference to details of the character here indicated, is not unimportant.

Lyons, N.Y., March 30 M. A. VEEDER

Ozone

MY attention has been drawn to a letter in your issue of January 13 (p. 248), respecting the production of ozonised air for respiration in pulmonary complaints. I beg to inform "W. H." that there is at present no convenient electrical apparatus devised for use in a room, that would electrify the air with sufficient power to be of much service. A simple plan for obtaining ozone in small quantities is to mix very gradually three parts of strong sulphuric acid with two parts of permanganate of potash in a jam-pot, and place the vessel under the bed. Ozone will be given off from this mixture for some weeks.

I should be glad to hear the experiences of "W. H." inhaling ozonised air "just sensible to the smell," as I am of opinion that this strength of ozone is rather too great.

Your correspondent is misled in supposing that the Engadine hotels possess appliances for ozonising the air of corridors, &c. It is only the Maloja Kursaal which has adopted my device for this purpose. The electric current used is taken off from one of the dynamos used for lighting. A short description of the plan is given in the third edition of my "Alpine Winter," p. 84.

Upper Engadine A. TUCKER WISE

Electrical Discharges in the Doldrums

I QUITE agree with the Hon. Ralph Abercromby as to the continuous electrical discharges in the doldrums; so is there a continuous discharge of rain. I do not, however, agree with him in thinking that the electrical discharges are in any way directly connected with earth-currents. I should say they are due to electrical discharges on the top of the shower clouds, unaccompanied by thunder. It would be interesting to know if travellers in the centres of Africa and South America have observed this phenomenon there.

DAVID WILSON-BARKER

Green Light at Sunrise and Sunset

MR. R. T. OMOND, of the Ben Nevis Observatory, in NATURE of February 24, p. 391, asks whether the cause of the green colour at sunset at sea is the sun shining *through* the water? This cannot be the cause, for I have many times observed this colour at sunrise behind the mountains Madonie or Copo Zaferano, which, from the Observatory, appear higher on the sea horizon than the sun's disk. That is to say, the phenomenon occurs when, for the observer, the sun is entirely above the marine horizon, and no part of the disk can shine through the water.

A. RICCÒ

Palermo Observatory

[This is a well known and obvious effect of atmospheric refraction.—ED.]

A Sparrow chasing Pigeons

"E. A. C." inquires in NATURE of last week (p. 536), whether any of your readers have observed the sparrow chasing pigeons. This habit of the sparrow is very common; I have myself often observed it, and I apprehend that few who keep pigeons have not frequently seen such attacks. The pugnacity of the sparrow did not appear to me to be the result of any previous quarrel with the pigeon, as I never saw the former attack the latter except on the wing, and always from underneath.

Chirbury, Beckenham, Kent, April 12 J. JENNER WEIR

A Question for Chemists

Is it known that a mixture of glycerine and permanganate of potassium will take fire spontaneously immediately after being mixed? If so, I should be glad of any reference to the fact.

Bradford WM. WEST

THE PARIS ASTRONOMICAL CONGRESS

THE International Congress called together by the French Government to take steps to obtain a photographic chart of the heavens was opened on Saturday at the Observatory of Paris, and, from the information which has reached us so far, it would seem that its labours are likely to have a result of the highest importance for the science of this and succeeding centuries. The following Directors of Observatories are already in Paris, or are expected: if half of them really come, there will be such a meeting of astronomers as has rarely been seen:—

Baillaud, Toulouse Observatory
Bakhuyzen, Leiden
Beuf, La Plata
Christie, Greenwich
Cruls, Rio de Janeiro
Donner, Helsingfors
Dunér, Lund
Folie, Brussels
Gill, Cape Town
Gyldèn, Stockholm
Krueger, Kiel
Oom, Lisbon
Perry, Stonyhurst
Peters, Clinton (U.S.A.)
Pujazon, San-Fernando
Rayet, Bordeaux
Russell, Sydney
Schoenfeld, Bonn
Struve, Pulkowa
Tacchini, Rome
Thiele, Copenhagen
Trépied, Algiers
Vogel, Potsdam
Weiss, Vienna

Besides these Directors of Observatories, and of course all the astronomical members of the Institute, there are other astronomers, such as Messrs. Common and Roberts from our own country, and Messrs. Lohse (from Germany), Winterhalter (from Washington), and Hasselberg (from Pulkowa), whose presence is most important.

The French Government, the Academy of Sciences (with Dr. Janssen as President), and Admiral Mouchez (the Director of the National Observatory of Paris), seem to have done all in their power to facilitate the labours, and even to provide for the comfort, of the various delegates and others representing the various nationalities; and at the opening ceremony the manner in which the Institute and Government are doing all they can was evidenced by the fact that the address which was delivered by M. Bertrand, the eminent mathematician, on behalf of the Academy of Sciences, was followed by another, made by M. Flourens, the Minister of Foreign Affairs.

They certainly manage these things better in France! Fancy a scientific meeting at Greenwich Observatory, addressed by the head of the English Foreign Office!

What M. Flourens said had better be given in his own words:—

Messieurs,—

J'ai l'honneur de vous souhaiter la bienvenue au nom de la France, qui vous offre ici sa cordiale hospitalité.

Je me félicite que cette mission me soit échue de vous complimenter au nom du gouvernement de la République, de vous remercier d'avoir accepté les invitations qui vous ont été adressées par l'éminent et sympathique directeur de notre Observatoire.

C'est une grande œuvre que celle que vous allez entreprendre, et, grâce aux lumières que vous nous apportez de tous les points du globe, mener à bonne fin. Dans la poursuite de cette œuvre, vous aurez, je n'en doute pas, l'appui de tous les gouvernements, qui sont animés aujourd'hui d'une noble émulation pour le développement de la science. En tout cas, le concours du gouvernement de la République française, au nom de laquelle j'ai l'honneur de parler, vous est dès à présent acquis.

Vous allez, dans une féconde et cordiale entente, jeter les bases de l'exécution d'une carte du ciel dont la précision dépassera de beaucoup non seulement tout ce que l'on avait réalisé, mais encore tout ce que l'on avait osé rêver jusqu'à ce jour. Par une merveilleuse application de la photographie, de cet art si riche en résultats imprévus, vous allez diriger l'œil humain dans des profondeurs où, à l'aide des plus puissants télescopes, on n'avait pas cru possible de le faire pénétrer. Le nombre des étoiles inconnues jusqu'ici, dont l'existence sera ainsi révélée, est incalculable.

Ce sera pour votre nom, messieurs, une gloire éternelle d'avoir apporté votre précieuse collaboration à l'inauguration de cette grande entreprise, et le jour de l'ouverture de ce congrès marquera dans les annales de la science humaine.

Une ère nouvelle s'ouvre pour l'astronomie physique comme pour l'astronomie mathématique, qui vont avoir à leur disposition un moyen d'investigation, de contrôle, de précision qui étendra dans une proportion indéfinie la fécondité de leurs recherches. Vous allez écrire la première page authentique des transformations et des modifications de la matière cosmique, c'est-à-dire l'histoire de l'univers lui-même.

Je voudrais complimenter, par leurs noms et par leurs œuvres, chacun des savants illustres qui sont réunis dans cette enceinte. Mais j'abuserais des précieux et trop courts instants de notre réunion. Nos hôtes trouveront bon que je les honore tous en la personne de leur doyen, de l'illustre M. Struve, dont le nom est si sympathique à la France et dont on fêtait naguère le vingt-cinquième anniversaire comme directeur du célèbre observatoire de Poulkova.

Agréez, messieurs, avec mes vœux les plus sincères pour la réussite de vos efforts, la nouvelle assurance du concours du gouvernement de la République.

Prof. O. von Struve replied to this address in a short and impressive speech, and the Conference proceeded to elect officers.

Admiral Mouchez, the Director of the Observatory, was elected Honorary President, and Prof. O. von Struve Acting President. As Vice-Presidents, Messrs. Auwers, Christie, and Fizeau were elected; as Secretaries, Messrs. Tisserand and Bakhuyzen, assisted by Dunér and Trépied.

The Conference then proceeded to pass the following resolutions:—

(1) The progress realised in astronomical photography renders it absolutely necessary that the astronomers of the present century should undertake a conjoint photographic record of the heavens.

(2) This work shall be undertaken at certain stations to be selected, and with instruments identical in all essential points.

(3) The principal objects sought to be attained shall be:—

(*a*) To record the general state of the heavens at the present time by obtaining data which will enable us to determine the position and brilliancy of all the stars down to a certain magnitude, to be hereafter agreed on, with the greatest precision possible; the magnitudes to be expressed according to some photographic standard to be hereafter determined.

(*b*) To fix upon the best means to utilise at the present time the various data furnished by photographic processes.

After these resolutions were passed, the Conference proceeded to appoint a Committee of nineteen members to consider the kind of instrument to be employed, and the lowest magnitude of star it will be necessary to register. The Committee appointed consists of the following astronomers:—MM. Auwers, Bakhuyzen, Christie, Common, Dunér, Fizeau, Gill, Paul Henry, Janssen, Kapteyn, Lœwy, Rayet, Roberts, Peters, O. von Struve, Tacchini, Thiele, Vogel, and Weiss. When this Committee has brought up its Report, the other questions will be considered by a number of Sections, to be appointed to consider and report upon them to the Conference.

Hospitality is not lacking to make the labours of the Conference as light as possible. Admiral Mouchez, who gave a *soirée* on the evening of the 19th, gives a banquet on the 24th. The astronomers are to be received by the President of the Republic, and also at the Théâtre Français by the members of the Institute, on Saturday. There is also to be a ball at the Hôtel Continental, given by Le Comité des Amis de Science.

We warmly congratulate French men of science upon the magnificent results obtained by their countrymen the Brothers Henry, which have been among the causes that have brought the Conference together. If all goes well, the work of the Conference will mark an epoch in the history of astronomy.

HOMERIC ASTRONOMY

I.

THE Homeric ideas regarding the heavenly bodies were of the simplest description. They stood, in fact, very much on the same level with those entertained by the North American Indians, when first brought into European contact. What knowledge there was in them was of that "broken" kind which (in Bacon's phrase) is made up of wonder. Fragments of observation had not even begun to be pieced in one with the other, and so fitted, ill or well, into a whole. In other words, there was no faintest dawning of a celestial science.

But surely, it may be urged, a poet is not bound to be an astronomer. Why should it be assumed that the author (or authors) of the "Iliad" and "Odyssey" possessed information co-extensive on all points with that of his fellow-countrymen? His profession was not science, but song. The argument, however, implies a reflecting backward of the present upon the past. Among unsophisticated peoples, specialists, unless in the matter of drugs or spells, do not exist. The scanty stock of gathered knowledge is held, it might be said, in common. The property of one is the property of all.

More especially of the poet. His power over his hearers depends upon his presenting vividly what they already perceive dimly. It was part of the poetical faculty of the Ithacan bard Phemius that he "knew the works of gods and men" ("Od," i. 338). His special function was to render them famous by his song. What he had heard concerning them he repeated; adding, of his own, the marshalling skill, the vital touch, by which they were perpetuated. He was no inventor: the actual life of men, with its transfiguring traditions and baffled aspirations, was the material he had to work with. But the life of men was very different then from what it is now. It was lived in closer contact with Nature; it was simpler, more typical, consequently more susceptible of artistic treatment.

It was accordingly looked at and portrayed as a whole; and it is this very *wholeness* which is one of the principal charms of primitive poetry. An irrecoverable charm; for civilisation renders existence a labyrinth of which it too often rejects the clue. In olden times, however, its ways were comparatively straight, and its range limited. It was accordingly capable of being embraced with approximate entirety. Hence the encyclopædic character of the early epics. *Humani nihil alienum.* Whatever men thought, and knew, and did, in that morning of the world when they spontaneously arose, found a place in them.

Now, some scheme of the heavens must always accompany and guide human existence. There is literally no choice for man but to observe the movements, real or apparent, of celestial objects, and to regulate his actions by the measure of time they mete out to him. Nor had he at first any other means of directing his wanderings upon the earth save by regarding theirs in the sky. They are thus to him standards of reference and measurement as regards both the fundamental conditions of his being—time and space.

This intimate connexion, and, still more, the idealising influence of the remote and populous skies, has not been lost upon the poets in any age. It might even be possible to construct a tolerably accurate outline-sketch of the history of astronomy in Europe without travelling outside the limits of their works. But our present concern is with Homer.

To begin with his mode of reckoning time. This was by years, months, days, and hours ("Od.," x. 469, xi. 294). The week of seven days was unknown to him; but in its place we find (in the "Odyssey," xix. 307) the triplicate division of the month used by Hesiod and the later Attics, implying a month of thirty, and a year of 360 days, corrected, doubtless, by some rude process of intercalation. A corresponding apportionment of the hours of night into three watches (as amongst the Jews before the Captivity), and of the hours of day into three periods or stages, prevails in both the "Iliad" and "Odyssey." The seasons of the year, too, were three—spring, summer, and winter—like those of the ancient Egyptians and of our Anglo-Saxon forefathers;[1] for the Homeric *Opora* was not, properly speaking, an autumnal season, but merely an aggravation of summer heat and drought, heralded by the rising of Sirius towards the close of July. It, in fact, strictly matched our "dog-days," the *dies caniculares* of the Romans. This rising of the dog-star is the only indication in the Homeric poems of the use of a stellar calendar such as we meet full-grown in Hesiod's "Works and Days." The same event was the harbinger of the Nile-flood to the Egyptians, serving to mark the opening of their year as well as to correct the estimates of its length.

The annual risings of stars had formerly, in the absence of more accurate means of observation, an importance they no longer possess. Mariners and husbandmen, accustomed to watch, because at the mercy of the heavens, could hardly fail no less to be struck with the successive effacements by, and re-emergences from, the solar beams, of certain well-known stars, as the sun pursued his yearly course amongst them, than to note the epochs of such events. Four stages in these periodical fluctuations of visibility were especially marked by primitive observers. The first perceptible appearance of a star in the dawn was known as its "heliacal rising." This brief glimpse extended gradually as the star increased its seeming distance from the sun, the interval of precedence in rising lengthening by nearly four minutes each morning. At the end of close upon six months occurred its "acronychal rising," or last visible ascent from the eastern horizon after sunset. Its conspicuousness was then at the maximum, the whole of the dark hours being available for its shining. To these two epochs of rising succeeded and corresponded two epochs of setting—the "cosmical" and the "heliacal." A star set cosmically when, for the first time each year, it reached the horizon long enough before break of day to be still distinguishable; it set heliacally on the last evening when its rays still detached themselves from the background of illuminated western sky, before getting finally immersed in twilight. The round began again when the star had arrived sufficiently far on the other side of the sun to show in the morning—in other words, to rise heliacally.

Wide plains and clear skies gave opportunities for closely and continually observing these successive moments in the revolving relations of sun and stars, which were soon found to afford a very accurate index to the changes of the seasons. By them, for the most part, Hesiod's prescriptions for navigation and agriculture are timed; and although Homer, in conformity with the nature of his subject, is less precise, he was still fully aware of the association.

His sun is a god—Helios—as yet unidentified with Apollo, who wears his solar attributes unconsciously. Helios is also known as Hyperion, "he who walks on high," and Elector, the "shining one." Voluntarily he pursues his daily course in the sky, and voluntarily he sinks to rest in the ocean-stream. Subject, however, at times to a higher compulsion. For, just after the rescue of the body of Patroclus, Here favours her Achaian clients by precipitating at a critical juncture the descent of a still unwearied and unwilling luminary ("Iliad," xviii. 239). On another occasion, however, Helios memorably asserts his independence, when, incensed at the slaughter of his sacred cattle by the self-doomed companions of Ulysses, he threatens to "descend into Hades, and shine among the dead" ("Od.," xii. 383). And Zeus, in promising the required satisfaction, virtually admits his power to abdicate his office as illuminator of gods and men.

Once only, the solstice is alluded to in Homeric verse. The swineherd Eumæus, in describing the situation of his native place, the Island of Syrie, states that it is over against Ortygia (Delos), "where are the turning-places of the sun" ("Od.," xv. 404). The phrase probably indicates the direction in which Delos lay from Ithaca, being just so much south of east as the sun lies at rising on the shortest day of winter. To those early students of Nature, the travelling to and fro of the points of sunrise and sunset, furnished the most obvious clue to the yearly solar revolution; so that an expression, to us somewhat recondite, conveyed a direct and unmistakable meaning to hearers whose narrow acquaintance with the phenomena of the heavens was vivified by immediate personal experience of them.

Selene first takes rank as a divine personage in the Homeric hymns. No moon-goddess is recognised in the "Iliad" or "Odyssey." Nor does the orbed ruler of "ambrosial night," regarded as a mere light-giver or time-measurer, receive all the attention that might have been expected. A full moon is, however, represented with the other "heavenly signs" on the shield of Achilles, and figures somewhat superfluously in the magnificent passage where the Trojan watch-fires are compared to the stars in a cloudless sky:

"Even as when in heaven the stars about the bright moon shine clear to see, when the air is windless, and all the peaks appear and the tall headlands and glades, and from heaven breaketh open the infinite air, and all stars are seen, and the shepherd's heart is glad; even in like multitude between the ships and the streams of Xanthos appeared the watch-fires that the Trojans kindled in front of Ilios."[1]

---

[1] Lewis, "Astr. of the Ancients," p. 11. Tacitus says of the Germans: "Autumni perinde nomen ac bona ignorantur" ("Germania," cap. xxvi)

Here, as elsewhere, the simile no sooner presents itself than the poet's imagination seizes upon and develops it without overmuch regard to the illustrative fitness of its details. The multitudinous effect of a thousand fires blazing together on the plain inevitably suggested the stars. But with the stars came the complete nocturnal scene in its profound and breathless tranquillity. The "rejoicing shepherd," meantime, who was part of it, would have been ill-pleased with the darkness required for the innumerable stellar display first thought of. And since, to the untutored sense, landscape is delightful only so far as it gives promise of utility, brilliant moonlight was added, for his satisfaction and the safety of his flock, as well as for the perfecting of that scenic beauty felt to be deficient where human needs were left uncared for. Just in proportion, however, as rocks, and peaks, and wooded glens appeared distinct, the lesser lights of heaven, and with them the fundamental idea of the comparison, must have become effaced; and the poet, accordingly, as if with a misgiving that the fervour of his fancy had led him to stray from the rigid line of his purpose, volunteered the assurance that "all the stars were visible"—as, to his mind and eye, they doubtless were.

Of the "vivid planets" thrown in by Pope there is no trace in the original. Nor could there be; since Homer was totally ignorant that such a class of bodies existed. This curious fact affords (if it were needed) conclusive proof of the high antiquity of the Homeric poems. Not the faintest suspicion manifests itself in them that Hesperus, "fairest of all stars set in heaven," is but another aspect of Phosphorus, herald of light upon the earth, "the star that saffron-mantled Dawn cometh after, and spreadeth over the salt sea" ("Iliad," xxiii. 226–27). The identification is said by Diogenes Laertius to have been first made by Pythagoras; and it may at any rate be assumed with some confidence that this elementary piece of astronomical knowledge came to the Greeks from the East, with others of a like nature, in the course of the sixth or seventh century B.C. Astonishing as it seems that they should not have made the discovery for themselves, there is no evidence that they did so. Hesiod appears equally unconscious with Homer of the distinction between "fixed" and "wandering" stars. According to his genealogical information, Phosphorus, like the rest of the stellar multitude, sprang from the union of Astræus with the Dawn ("Theogony," 381), but no hint is given of any generic difference between them.

There is a single passage in the "Iliad," and a parallel one in the "Odyssey," in which the constellations are formally enumerated by name. Hephæstus, we are told, made for the son of Thetis a shield great and strong, whereon, by his exceeding skill, a multitude of objects were figured.

"There wrought he the earth, and the heavens, and the sea, and the unwearying sun, and the moon waxing to the full, and the signs every one wherewith the heavens are crowned, Pleiads, and Hyads, and Orion's might, and the Bear that men call also the Wain, her that turneth in her place, and watcheth Orion, and alone hath no part in the baths of Ocean" ("Iliad," xviii. 483–89).

The corresponding lines in the "Odyssey" occur in the course of describing Ulysses' voyage from the isle of Calypso to the land of the Phæacians. Alone, on the raft he had constructed of Ogygian pine-wood, he sat during seventeen days, "and cunningly guided the craft with the helm; nor did sleep fall upon his eyelids, as he viewed the Pleiads and Bootes, that setteth late, and the Bear, which they likewise call the Wain, which turneth ever in one place, and keepeth watch upon Orion, and alone hath no part in the baths of Ocean" ("Odyssey," v 271–75).

The sailing-directions of the goddess were to keep the Bear always on the left—that is, to steer due east.

It is clear that one of these passages is an adaptation from the other; nor is there reason for hesitation in deciding which was the model. Independently of extrinsic evidence, the verses in the "Iliad" have the strong spontaneous ring of originality, while the Odyssean lines betray excision and interpolation The "Hyads and Orion's might" are suppressed for the sake of introducing Bootes. Variety was doubtless aimed at in the change; and the conjecture is at least a plausible one, that the added constellation may have been known to the poet of the "Odyssey" (admitting the hypothesis of a divided authorship), though not to the poet of the "Iliad." Known, that is, in the sense that the stars comprising the figure of the celestial Husbandman had not yet, at the time and place of origin of the "Iliad," become separated from the anonymous throng circling in the "murk of night."

The constellation Bootes was invented to drive the Wain, as Arctophylax to guard the Bear, the same group in each case going by a double name. For the brightest of the stars thus designated we still preserve the appellation Arcturus (from *arktos*, bear, *ouros*, guardian), first used by Hesiod, who fixed upon its acronychal rising, sixty days after the winter solstice, as the signal for pruning the vines ("Works and Days," 564–70). It is not unlikely that the star received its name long before the constellation was thought of, forming the nucleus of a subsequently formed group. This was undoubtedly the course of events elsewhere; the Great and Little Dogs, for instance, the Twins, and the Eagle (the last with two minute companions) having been individualised as stars previous to their recognition as asterisms.

There is reason to believe that the stars enumerated in the "Iliad" and "Odyssey" constituted the whole of those known by name to the early Greeks. This view is strongly favoured by the identity of the Homeric and Hesiodic stars. It is difficult to believe that, had there been room for choice, the same list *precisely* would have been picked out for presentation in poems so widely diverse in scope and origin as the "Iliad" and "Odyssey" on the one side, and the "Works and Days" on the other. As regards the polar constellations, we have positive proof that none besides Ursa Major had been distinguished. For the statement repeated in both the Homeric epics, that the Bear *alone* was without part in the baths of Ocean, implies, not that the poet veritably ignored the unnumbered stars revolving within the circle traced out round the pole by the seven of the Plough, but that they still remained a nameless crowd, unassociated with any terrestrial object, and therefore attracting no popular observation.

The Greeks, according to a well-attested tradition, made acquaintance with the Lesser Bear through Phœnician communication, of which Thales was the medium Hence the designation of the group as *Phoinike*. Aratus (who versified the prose of Eudoxus) has accordingly two Bears, lying (in sailors' phrase) "heads and points" on the sphere, while he expressly states that the Greeks still (about 270 B.C.) continued to steer by *Helike* (the Twister, Ursa Major), while the expert Phœnicians directed their course by the less mobile *Kynosoura* (Ursa Minor). The absence of any mention of a Pole-star seems at first sight surprising. Even the Iroquois Indians directed their wanderings from of old by the one celestial luminary of which the position remained sensibly invariable (Lafitau, "Mœurs des Sauvages Américains,"

---

[1] "Iliad," viii 551–57. Mr. Andrew Lang's admirable prose-versions are employed throughout this article.

p. 240). Yet not the gods themselves, in Homer's time, were aware of such a guide. It must be remembered, however, that the axis of the earth's rotation pointed, 2800 years ago, towards a considerably different part of the heavens from that now met by its imaginary prolongation. The precession of the equinoxes has been at work in the interval, slowly but unremittingly shifting the situation of this point among the stars. Some 600 years before the Great Pyramid was built, it was marked by the close vicinity of the brightest star in the Dragon. But this in the course of ages was left behind by the onward-travelling pole, and further ages elapsed before the star at the tip of the Little Bear's tail approached its present position. Thus the entire millennium before the Christian era may count for an interregnum as regards Pole-stars. Alpha Draconis had ceased to exercise that office; Alruccabah had not yet assumed it.

The most ancient of all the constellations is probably that which Homer distinguishes as never-setting (it then lay much nearer to the pole than it now does). In his time, as in ours, it went by two appellations—the Bear and the Wain. Homer's Bear, however, included the same seven bright stars constituting the Wain, and no more; whereas our Great Bear stretches over a sky-space of which the Wain is only a small part, three of the striding monster's far-apart paws being marked by the three pairs of stars known to the Arabs as the "gazelle's springs." How this extension came about, we can only conjecture; but there is evidence that it was fairly well established when Aratus wrote his description of the constellations. Aratus, however, copied Eudoxus, and Eudoxus used observations made—doubtless by Accad or Chaldean astrologers—above 2000 B.C.[1] We infer, then, that the Babylonian Bear was no other than the modern Ursa Major.

But the primitive asterism—the Seven Rishis of the old Hindus, the Septem Triones of the Latins, the Arktos of Homer—included no more than seven stars. And this is important as regards the origin of the name. For it is impossible to suppose a likeness to any animal suggested by the more restricted group. Scarcely the acquiescent fancy of Polonius could find it "backed like a weasel," or "very like a whale." Yet a weasel or a whale would match the figure equally well with, or better than, a bear. Probably the growing sense of incongruity between the name and the object it signified may have induced the attempt to soften it down by gathering a number of additional stars into a group presenting a distant resemblance to a four-legged monster.

The name of the Bear, this initial difficulty notwithstanding, is prehistoric and quasi-universal. It was traditional amongst the American-Indian tribes, who, however, sensible of the absurdity of attributing a conspicuous protruding tail to an animal almost destitute of such an appendage, turned the three stars composing it into three pursuing hunters.

The same constellation figures, under a divinified aspect, with the title *Otawa*, in the great Finnish epic, the "Kalevala." Now, although there is no certainty as to the original meaning of this word, which has no longer a current application to any terrestrial object, it is impossible not to be struck with its resemblance to the Iroquois term *Okowari*, signifying "bear," both zoologically and astronomically (Lafitau, *op. cit.*, p. 236). The inference seems justified that *Otawa* held the same two meanings, and that the Finns knew the great northern constellation by the name of the old Teutonic king of beasts.

It was (as we have seen) similarly designated on the banks of the Euphrates; and a celestial she-bear, doubtfully referred to in the Rig-Veda, becomes the starting-point of an explanatory legend in the Râmâyana. (De Gubernatis, "Zoological Mythology," vol. ii. p. 109). Thus, circling the globe from the valley of the Ganges to the great lakes of the New World, we find ourselves confronted with the same sign in the northern skies, the relic of some primæval association of ideas, long since extinct.

Extinct even in Homer's time. For the myth of Callisto (first recorded in a lost work by Hesiod) was a subsequent invention—an effect, not a cause—a mere embroidery of Hellenic fancy over a linguistic fact, the true origin of which was lost in the mists of antiquity.

There is, on the other hand, no difficulty in understanding how the Seven Stars obtained their second title of the Wain, or Plough, or Bier. Here we have a plain case of imitative name-giving—a suggestion by resemblance almost as direct as that which established in our skies a Triangle and a Northern Crown. Curiously enough, the individual appellations still current for the stars of the Plough, include a reminiscence of each system of nomenclature—the legendary and the imitative. The brightest of the seven, α Ursæ Majoris, the Pointer nearest the Pole, is designated *Dubhe*, signifying, in Arabic, "bear"; while the title *Benetnasch*—equivalent to *Benât-en-Nasch*, "daughters of the bier"—of the furthest star in the plough-handle, perpetuates the lugubrious fancy, native in Arabia, by which the group figures as a corpse attended by three mourners.

RAINBAND OBSERVATIONS AT THE BEN NEVIS OBSERVATORY

RAINBAND spectroscopy is one of the extra subjects taken up at the Ben Nevis Observatory, along with the usual meteorological routine. At every hour, when there is sufficient light, the intensity of the rainband is observed and recorded, and now, the mean daily rainband forms one of the items in the Ben Nevis weather report in the daily newspapers. The scale in use is practically the same as that used by Dr. Mill, of the Granton Marine Station, and described by him in a paper to the Royal Society of Edinburgh (Proc. R.S.E., 1882–84). This scale is in the spectrum itself—a great convenience—being the Fraunhofer lines E, *b*, and F of the solar spectrum. After a preliminary set of observations had been made, in various types of weather, for the purpose of determining the relative intensity of these lines, a numerical value was given to each, namely, to E, 2; to *b*, 4; and to F, 7. After a little practice, it is quite easy to estimate the values less than 2, which often occur, and the values above 7, which very seldom occur. With this scale, the intensity or darkness of the rainband and D line taken together is compared, and the numerical value of its scale-equivalent entered in the register. The instrument used is one of Hilger's rainband pocket spectroscopes, and the part of the sky always observed is between 30° and 40° above the south-western horizon.

The results obtained in 1885 were communicated to the Scottish Meteorological Society, and are published in their Journal for 1886 (see NATURE, vol. xxxiii. p. 622). In 1886, over 3000 observations were made, and the relative frequency with which each number of the scale was observed will convey an idea of the intensity of the rainband on Ben Nevis. The percentage of observations of each number is as follows:—

Rainband	0	1	2	3	4	5	6	7
Percentage ...	24	31	27	8	7	1	1	1

The mean of all the observations gives a rainband of 1·7. Now at sea-level, according to Dr. Mill, the rainband is seldom or never less than E, that is, than 2 on our scale. Hence the mean rainband on the Ben is about equal to the minimum at sea-level. About 80 per cent. of these observations were made when the Ben was enveloped in fog or mist. The only effect fog or mist has upon the rainband is that its intensity is the same in every possible direction, whereas in clear weather, as is well known, it is generally greatest at the horizon and least at the zenith. But as the rainband in fog or mist has been found to be equal to that which is observed in clear weather at an altitude of 30° or 40°—the altitude of that part of sky always observed—the presence or absence of fog and mist has been ignored in working up the observations.

In forecasting the weather for the surrounding low-levels, the rainband observed here, together with similar observations at Fort William, would probably be of great value, but its forecasting power for the summit alone is limited. The lower values generally show indications of rain several hours before it comes on, but the higher values simply indicate a continuation of the heavy rainfall by which they are invariably accompanied. To show that the rainfall increases with the successive numbers of the scale, the mean hourly rainfall has been computed, for each scale value, from the rainfall of the three hours and twelve hours after noon. For the observations of 1885, the mean daily rainband was used. In 1886, each individual observation was taken into account, and, for each number of the scale, the mean rainfall was computed from the rainfall of the three hours after each observation. As the results differ in some respects, they are here given for each year separately :—

Rainband		0	1	2	3	4	5 and upwards
Rainfall (inches)	1885 ..	·000	·006	·016	·029	·050	·106
	1886...	002	·006	·012	·016	·027	·076

Owing to the fewness of observations of the numbers 5, 6, and 7, they have been grouped together. The higher values are followed by a rainfall which is proportionally far too high, owing, no doubt, to the fact that these higher values are only observed during the passage of cyclonic disturbances laden with moisture from the Atlantic, when a great amount of this moisture only comes into the spectroscopic field in a condensed state, when it is forced to ascend so as to pass the summit, and consequently does not affect the rainband, but causes a very heavy rainfall. The moisture that ascends the mountain, not being detected below by the spectroscope here, is a constant source of disparities in the agreement of rainband and subsequent rainfall. The fact that our mean rainband is not greater than 1·7, and that the amounts of rainfall were, for 1885, 146·497 inches, and for 1886, 107·847 inches, clearly indicates that a great part of our rainfall is due to the condensation of the moisture that is forced up from below the level of the summit.

In comparing rainband with subsequent rainfall, the temperature of the air at the time of observation, as well as the variation in the temperature, must be taken into account. With the view of ascertaining the relations between rainband, subsequent rainfall, and temperature, the mean hourly rainfall for the three hours after an observation, for each number of the rainband scale, and for every 5° of temperature from 15° to 50°, has been calculated, and the results for rainbands of values 1, 2, and 3, are as follows :—

Temperature		15°	20°	25°	30°	35°	40°	45°	50°
Rainband	1 ..	·003	·005	·010	·006	·006	·004	·000	·000
	2	·005	·010	024	·015	012	·006	·003	·000
	3 ..	·007	·013	·026	·019	·016	·015	·009	·003

The means for temperatures of 25° and upwards show that for any one rainband, when the temperature rises the rainfall decreases, and when the temperature falls the rainfall increases. The results being as yet only tentative, it cannot be definitely stated by how much the mean hourly rainfall increases or decreases per degree of fall or rise in the temperature, for any one value of the rainband. The means for temperatures below 25° seem to indicate that a fall in the temperature causes a decrease in the rainfall, which is not at all probable. If it be the case that low temperatures do not affect the absorbing powers of aqueous vapour, which is not likely, the small amount of rainfall at these low temperatures may be due to the necessarily unsatisfactory measurements of precipitation obtained from the rain-gauge when the temperature is below 32°. In truth, snowfall and rainfall as measured by the rain-gauge, can hardly be compared with each other. For a full account of these and other questions of rainfall here, see Mr. Omond's articles and also Mr. Buchan's "Meteorology of Ben Nevis" in the Journal of the Scottish Meteorological Society for the last two years.

The mean rainbands at the different temperatures are :—

Temperature	15°	20°	25°	30°	35°	40°	45°	50°
Rainband ..	0·4	1·1	1·1	1·5	1·9	2·4	2·5	2·3

The greatest number of observations at any one temperature was 724 at 30°, and the least 35 at 50°.

The reason why so many observations were made in 1886 was to find whether there was any daily variation in the rainband. That there is a slight variation will be seen from the following results, which are for the summer months only, viz. :—

Hour	6	7	8	9	10	11	12 noon
Rainband	1·4	1·4	1·6	1·5	1·6	1·6	1·7
Temperature	32°·0	32°·3	32°·7	33°·2	33°·5	34°·0	34°·4

Hour	13	14	15	16	17	18
Rainband	1·7	1·7	1·8	1·7	1·8	1·7
Temperature	34°·8	35°·0	35°·0	34°·9	34°·7	34°·3

The rise in the rainband from 6 a.m. till 3 p.m. following the temperature, points to the cause of this daily variation as being the expansion of the lower atmosphere by the rising temperature, and the consequent raising of the vapour above the level of the Ben. This is almost the same cause to which Mr. Buchan ascribes the rise in the barometric pressure for the same daily period. Prof. Piazzi Smyth says that the rainband does not increase for a rise of temperature *at sea-level*, because the total quantity of vapour over the place of observation is pretty constant (Journal Scot. Met. Soc., vol. v.). But over this summit the quantity of vapour is not constant, but varies, and the rainband varies with it.

Remarkable variations in the rainband occur in the course of a single day, often amounting to 3, and sometimes to 5 and 6. On March 26, 1886, when a cyclone was passing to the north of the Observatory, the rainband varied from 6 at 10 a.m., to 3 at 12 noon, and to 1 at 5 p.m. The strongest mean for any one day was 8 on January 1, 1886, while a mean of 0 has frequently occurred. On December 18, 1885, a rainband, estimated at 12, was observed on the rising sun—this was one of the noted "fore-glow" mornings. In anticyclonic weather, which is characterised by great dryness of the air, with all the clouds at lower levels, a strong rainband is always obtained from the layer of air close over the clouds, in summer, when not a trace is detected at the usual height of observation; but in similar weather in winter the rainband is often entirely absent, even over the clouds. It is noteworthy that on days with little or no rainband, when not actually looking at the sun, the spectrum as a whole is darker than usual, and on days with strong rainbands, the parts of the spectrum not occupied by lines are brighter than usual. In a certain type of weather, when the rain-gauge completely fails to record the precipitation, the rainband always indicates the presence in the air of the vapour which gives it. This occurs when snow-crystals are deposited with low temperatures and strong winds, as described in NATURE (vol. xxxi. p. 532). The importance of rainband observations will be greatly increased when similar series can be undertaken at the sea-level simultaneously with those on the summit of Ben Nevis.

A. RANKIN

DO SCORPIONS COMMIT SUICIDE?

CORRESPONDENTS of NATURE have repeatedly raised the question whether there is any truth in the old legend that a scorpion, when placed within a ring of red-hot embers, will, after making futile efforts to pass the fiery circle, deliberately kill itself by inflicting a wound with a sting in its own head. Surgeon-General Bidie, of Madras (vol. xi. p. 29), Dr. Allen Thomson (vol. xx. p. 577), and Mr. Gillman (vol. xx. p. 629), have answered the question in the affirmative. The other side has been taken by Mr. Hutchinson (vol. xxi. p. 226), Mr. Curran (vol. xxi. p. 325), and Mr. Lloyd Morgan (vol. xxvii. p. 313). Mr. Hutchinson maintained that the animals experimented on by Mr. Gillman had died from excessive heat. To this Mr. Gillman replied, that the temperature in the centre of such a circle of glowing charcoal as he used does not exceed 50° C.

The subject has lately been thoroughly investigated by Mr. Alfred G. Bourne, Professor of Biology in the Presidency College, Madras; and the results of his observations have been set forth in a paper communicated to the Royal Society by Prof. Ray Lankester. Some of the details of his experiments are not very pleasant reading, but it must be remembered that the question is one of considerable importance, because, if it could be proved that the scorpion commits suicide, its impulse to do so would be, as Mr. Romanes has pointed out, "a unique case of an instinct detrimental alike to the individual and to the species."

One of the arguments used to disprove the existence of the supposed instinct is, that it is physically impossible for a scorpion to sting itself in a vulnerable place. Mr. Bourne shows that this statement is inaccurate. If, he says, a dead scorpion be taken which is quite limp and not in a state of rigour, it will be easily seen that the last four segments of the tail are about the only portions of the body, whether on the dorsal or ventral surface, where a scorpion could *not* sting itself. Further, if two fighting scorpions be watched, it will be seen that the extent to which the sting can be moved about is perfectly wonderful. Moreover, he has noticed that, when the scorpion is placed in very unpleasant circumstances, it not unfrequently lashes its tail about and causes actual penetration of the sting. If, for instance, the rays of a burning-glass be concentrated on any part of the body, the scorpion brings its sting there, and tries to strike away the source of irritation. Occasionally its efforts become more and more frantic, and the point of the sting catches somewhere. The scorpion, however, does not die unless the heat is concentrated on the back. In that case it soon succumbs, even if the sting has been tied down or previously removed.

The most important of Mr. Bourne's propositions is that the poison of a scorpion is quite powerless to kill the same individual, or another individual of the same species, or even scorpions of other species. If this proposition is established, there can, of course, be no further controversy about the matter. *A priori*, it is not improbable, for Sir Joseph Fayrer has shown that the cobra poison will not affect a cobra. Mr. Bourne frequently took a scorpion in his hand, and, holding the sting between a pair of forceps, pricked the scorpion with the sting and squeezed out its poison. There was a little bleeding from the wound, but in every case the scorpion lived for days. He also tried stinging one scorpion with another, using in the first instance specimens of the same species, then specimens of different species. Occasionally, he thinks, the stung individual became a trifle sluggish, but it never died from the sting. In order to make sure that his method of squeezing out the poison was perfectly effective, Mr. Bourne, after stinging a scorpion, sometimes continued to hold the sting, and, taking a cockroach, squeezed out into it some more of the poison. The cockroach invariably became very sluggish at once, and died in an hour or so. He also used a large cricket, stinging it in the femur of the large hind-leg; that leg became paralysed. When the animal was stung in the same place on both sides, both the hind-legs became useless, and it crawled away on the two anterior pairs of legs. Stung in the thorax it became quite torpid; when placed on its back it was not able to turn over. After considerable search, Mr. Bourne procured some specimens of *Thelyphonus*, which he chose as being the nearest relatives of the scorpions. He stung these in his usual method, and in each case they died within six seconds. He then tried some spiders, and they died in a few minutes when well stung. The slower general action in cockroaches and crickets is probably, he supposes, to be explained by the very inefficient circulation of the blood in insects as compared with Arachnida.

In all cases of artificial stinging Mr. Bourne took especial care to avoid mechanical injury to the nerve ganglia. And he tried puncture without the introduction of scorpion poison. Using large insects for this purpose, he obtained complete freedom from ill effects when using simple puncture, whereas the same species of insects when punctured with introduction of scorpion poison were instantly paralysed, and died in half an hour. He also procured two small shore crabs. One he punctured between two joints of the great chela of one side; several drops of blood exuded, but they coagulated, and the crab remained well. The second he stung in the same place, with scorpion's sting, squeezing it to insure poisoning. The claw was immediately paralysed, and the crab gradually became torpid, and died in less than an hour.

When a number of scorpions are kept together in captivity, it is not difficult to induce a couple to fight. Mr. Bourne isolated such a couple, and they fought on and off for two days, during which time each repeatedly stung the other. On another occasion he separated two scorpions which had been fighting, and which had repeatedly stung one another. They lived perfectly well.

Apropos of Mr. Gillman's remarks about the actual temperature to which the scorpion is subjected in the "fiery circle," Mr. Bourne tried this experiment. He placed a scorpion and a cockroach (for comparison) in an incubator with glass sides, and gave them a piece of wood to walk about upon, and gradually raised the temperature. At 40° C. both seemed uncomfortable, and the cockroach performed a sort of licking action on all its legs and antennæ. At 45° C. the scorpion became very sluggish, and at 50° C. it was nearly dead. A large furious scorpion before the experiment, it now lay on its back and did not attempt to get up. Mr. Bourne took it out and gave it a cold bath, and put it in a cool earthenware vessel; and in the course of two hours it recovered. The cockroach was left in the incubator till the temperature reached 52° C. When nearly dead, it was taken out, and very gradually recovered. To try the effect of a wet heat, a scorpion and a cockroach were placed in water at 43° C., and they both died almost immediately, whereas they would both have lived in cold water for hours.

The inference drawn by Mr. Bourne from his experiments is that scorpions do not commit suicide, and that when they die within a ring of fire, heat is the cause of death. After he had reached this conclusion he was told that according to some authorities inclosure in a circle of oil, or inclosure under an inverted tumbler, will cause a scorpion to kill itself. He accordingly placed a scorpion on a plate within a ring of cocoa-nut oil. It calmly walked through. He placed another scorpion on a plate, and round the edge a thick roll of rag dripping with kerosene oil. The animal walked out over the rag. When daubed with oil, it appeared uncomfortable, but did nothing remarkable. The experiment with an inverted tumbler was made, and gave the same negative result.

THE MYTHICAL ZOOLOGY OF THE FAR EAST

A SHORT time ago the British Museum acquired a comprehensive collection of Japanese and Chinese pictures, made by Mr. William Anderson, for some years medical officer to the British Legation in Tokio. This gentleman's magnificent work on the "Pictorial Arts of Japan" has already been noticed in these columns; and he has just placed students of the arts of the Far East under an additional debt of gratitude to him by the preparation of a catalogue of his collection in the British Museum, which has just been published by the Trustees of that institution. With this volume, except for a special purpose, we have nothing to do; but it is impossible to glance through it without being struck by the amount of labour which the author has devoted to his dissertations on the various schools of painting, to his descriptions of characteristic examples of these schools, and to his explanation of the motives which inspired the artists. The word "catalogue" is a modest one to employ in describing the work, for though it contains the numbers and names of the pictures, this is the least part of its contents.

Amongst the motives of the artists of China and Japan, mythical zoology held a very important place; it evidences, says Mr. Anderson, "a courage of invention almost unparalleled in the pseudo-science of Oriental races." It holds, too, a disproportionate place in the folk-lore and superstitions of the people of both countries. Yet it has scarcely received any attention in Europe. In Prof. Angelo de Gubernatis's great work on "Zoological Mythology" there is but a single reference to China, and none at all to Japan, while the myths of Aryan nations occupy the greater part of his volumes. Here and there in books relating to the countries of Eastern Asia scanty references to popular myths respecting animals are found, but, so far as we are aware, Mr. Anderson's is the first work which gives any adequate conception of the marvellous extent of this species of lore amongst the Chinese and Japanese. As the latter owe their art, literature, and religion to China, so they owe also their scientific myths. The Chinese have developed mythical zoology to a greater extent than any other nation. "Their literature teems with strange conceits, some of which appear to be transcripts of local folk-lore, others appertain to Buddhism or Taoistic legends, and others are accepted as sober facts of natural history." These have almost all been adopted and improved in treatment by the Japanese.

Mr. Anderson divides the anthropological myths into three classes:—

(1) Persons born of woman with or without divine agency, who develop magical powers, work miracles, and attain a fabulous longevity.

(2) Those distinguished by physical peculiarities of a fabulous nature. Amongst these are giants; dwarfs; perforated men, who are conveyed about by coolies by means of poles put through holes which conveniently exist in their bodies for this purpose; stomachless men, who, according to popular belief, "dare not laugh for they have no sides to hold"; men with enormously long legs, and those with similarly long arms; men with tails, who carefully dig holes where they sit in order to provide a receptacle for the appendage; and many other extraordinary beings, all of which are truthfully described, from Chinese works of authority and repute, in the great Japanese encyclopædia *Wa-Kan-San-Sai dsu-yé*.

(3) Transitional beings, who combine with human elements parts naturally appertaining to the lower animals: such are feathered men; those with human faces, but the wings and beak of a bird; mermen, who have human heads and arms attached to the body of a fish, and learn the secrets of the deep from the murmuring hollow of the Conchifer. To this section also belongs the vampire bride who lures men to her deadly embraces till she has drained away their life-blood.

Mythical animals are similarly classified:—

(1) Those without any remarkable peculiarities of conformation, but gifted with supernatural attributes. Thus the tiger is classed in Chinese mythology as one of the supernatural animals, the king of beasts, and the representative of the masculine or active principle of Nature. It attains the age of a thousand years, and after passing the half of this term its hair becomes white. It is sometimes seen in association with the dragon, apparently as the emblem of the power of faith; it is also regarded as the type of wisdom, and in illustration of this attribute Mr. Anderson gives a story (p. 51) which has a familiar analogy in European folk-lore. The fox, again, is the demon of mischief, with the power of changing his shape at will, but ever with some evil design on the comfort of mankind. When he reaches the age of fifty, Mr. Anderson tells us, he is able to accomplish at will his most favourite and baneful metamorphosis into the resemblance of womankind; at a hundred he can take the shape either of a young and beautiful girl, or of a wizard strong in all the powers of magic; and when he reaches the term of a thousand years he becomes a Celestial Fox, characterised by a golden colour and nine tails, and may be admitted to heaven. But it appears he does not always avail himself of this privilege, for the possession of the extra tails only gives him an augmented cunning and capacity for wickedness. The tortoise also attains a marvellous longevity, and is variously represented as the embodiment of a star in Ursa Major, and as a descendant of the first dragon. In Hindoo mythology the tortoise supports the elephant which supports the world; in Japanese art it is represented as bearing on its back the mountain abode of the immortals. The horse is also associated with longevity, and it is still a popular belief that the female is delivered of its progeny through the mouth. The crane is one of the commonest figures in Japanese art; in Chinese mythical zoology there are four varieties, distinguished by their colours; they all live to a fabulous age, and after completing six hundred years are superior to the necessity of other sustenance than water. Many other notices of animals belonging to this class are scattered throughout Mr. Anderson's book in connection with pictures in which they are represented.

(2) Animals differing from their fellows only in size, or in alterations of the due number of parts. Such are serpents eight hundred feet long, which devour elephants; nine-tailed foxes; the four-eared monkey which heralds the deluge; the fish with ten bodies and one head, whose flesh is a sure preventive of boils; and many others.

(3) Creatures made up by the amalgamation of parts of various animals. Amongst these composite monsters the principal is the dragon, which, according to the Japanese encyclopædia already mentioned, has the head of a camel, the horns of a deer, the eyes of a demon, the ears of an ox, the body of a serpent, the scales of a carp, and the claws of an eagle. It is not necessary to say more by way of description, for it is the most familiar object in the art of China and Japan. It is treated by writers of the last century as really existing. It becomes at will, according to a Chinese author of the seventh century B.C., reduced to the size of a silkworm, or swollen till it fills the space of heaven and earth. "In Chinese Buddhism it plays an important part, either as a force auxiliary to the law, or as a malevolent creature to be converted or quelled." It is a guardian of the faith, an attribute of saintly or divine personages, an enemy of mankind, an emblem of majesty, the presiding genius of rainfall, and a symbol of time and place, giving its name to certain days and years, and to a point of the compass. Many more details about this extraordinary creature will be found scattered through Mr. Anderson's book, especially on pp. 48 *et seq.* The *kilin* or *kirin*, "the noblest form of the animal creation,

and an emblem of perfect good," also belongs to this class. It has the body of a deer, the tail of an ox, and a single horn, so that it resembles the unicorn. The phœnix is another animal of this kind, with the head of a pheasant, the beak of a swallow, the neck of a tortoise, and the outward resemblance of a dragon. It is regarded as an omen of good, and heralds the advent of a beneficent reign. "In works of art it is a nondescript bird of gorgeous plumage, intermediate between that of the peacock and bird of paradise, and bears flame-like appendages where the neck joins the body."

All the creatures referred to here, and many more belonging to one or other of the classes of zoological myths, are represented pictorially in the *Wa-Kan-San-Sai dzu-yé*, already mentioned, and in the ***Mangwa*** of Hokusai, a book to which access can be obtained without difficulty in most of the capitals of Europe.

To the mythical animals already mentioned, which are common to China and Japan, the Japanese have added some of their own invention. Such are serpents, giant centipedes, monster devil-fishes; earth-spiders, probably representing the troglodytes of old Japan; the raccoon-faced dog, which possesses in a minor degree the evil powers and tendencies of the fox; the wolf-like animal which produces thunder; the "whirling neck," or being which has the power of so elongating the neck that the head appears in places remote from the body; the man-devouring ***kappa***, which frequents rivers and ponds, and politely challenges wayfarers to single combat; and many other equally strange creatures. An outline sketch of Japanese demonology will be found at p. 59, and a striking myth of a demon spider at p. 109.

Enough, however, has been said to show that if Mr. Anderson, in his catalogue and larger work on the "Pictoral Arts of Japan," has revealed to British readers a new and most important branch of art, he has incidentally indicated to his readers a new world of myth, which has hitherto found no place in the consideration of students of comparative mythology in Europe, but which can now be no longer neglected. Mr. Anderson of course treats it almost solely in its relation to art, but he informs the reader in every case where further and more detailed information may be obtained. The task of tracing these myths to their source and of finding analogies elsewhere is one for the scientific inquirer. Mr. Anderson has done the more laborious part of the work in bringing them together. He also suggests that very many of them will be found to have their homes in India, and to have spread with the doctrines of Buddha to China and other far eastern countries. One great advantage which the student of the zoological and other myths of China and Japan will have is that in the exhibition of the Anderson Collection, which is shortly to be opened at the British Museum, he will be able to see in the most graphic form the conceptions of successive generations of artists of the beings to which the myths relate—an advantage which could not be obtained even in the countries themselves without considerable expenditure of money, time, and labour. It only remains to be said that we have adopted Mr. Anderson's classifications, and in many instances have employed his own words in the descriptions of the myths scattered in so much profusion throughout the catalogue.

NOTES

We regret to have to announce the death, on Good Friday, at the Nice Observatory, of M. Thollon, the eminent spectroscopist. Few men devoted to spectroscopic inquiry have worked so unceasingly and successfully; and in him Science loses one of the most single-minded of her votaries. He has been cut off in the midst of his labours, which, especially since his location at M. Bischoffsheim's magnificent observatory and the completion of the spectroscopic installation there, have borne such rich fruit in the shape of a method of sorting out the telluric from the true solar lines (a method slightly modified by Cornu), and of a map of the solar spectrum as observed by the new form of spectroscope of his own invention, which vastly surpasses in dispersion and purity of image anything that preceded it. Dr. Thollon has not only worked at Nice, but at the Pic du Midi and the Paris Observatory; he was also one of the observers of the total solar eclipse in Egypt in 1882. In all his wanderings, as in his work, he made many friends, and all who knew him will mourn his loss, not only as a man of science, but as one possessing, above the ordinary degree, a true and genial nature.

On March 5 a drawing-room meeting for the promotion of technical education was held at the house of Mr. E. C. Robins, under the presidency of Prof. Huxley. A Memorandum of the proceedings has now been printed for private circulation. An address on the technical training at the Central Institution at South Kensington was delivered by Prof. Ayrton. The address was followed by a discussion, in which Prof. Silvanus Thompson, Mr. Brewin, Prof. Perry, Prof. Henrici, and others took part In summing up the debate, Prof. Huxley remarked that something had been said about rivalry between the Central Institution and the Finsbury School. That most excellent and vigorous school which the City and Guilds Institute had established at Finsbury was chiefly intended to give primary technical instruction to workmen and others who could snatch only a few hours a week from their daily labour for the purpose of receiving it. The Central Institution, on the other hand, was chiefly intended for the advanced instruction of persons who could give up their time for one or more years to the higher branches of technology. Exhibitions enabled the promising student of the schools at Finsbury and elsewhere to pass to the Central Institution, and profit by the advantages it offered him. To talk of rivalry between the two was like talking of a rivalry between Eton and Cambridge. No doubt the day would come when a score of such schools as that at Finsbury would be sending their picked scholars to the Central Institution; but, before that day could come, the organisation of the Central Institute must be so far completed that it could receive them and deal with them. A great deal had been said about the 100,000*l*. or 150,000*l*., or whatever it was, that had already been spent on the Central Institution, and of the 10,000*l*. a year that it cost. He begged leave to repeat that which he had said elsewhere, that if in the course of the next ten years the City and Guilds Institute could succeed in catching and training another Faraday or Whitworth or Armstrong, he would from a mere commercial point of view be worth all the expenditure initial and assured.

A highly interesting series of experiments has recently been successfully carried out by M. Olszewski. The more permanent gases have not only been liquefied at pressures averaging only 740 mm. by aid of excessively low temperatures, but the boiling-points, melting-points, and densities of these so-called gases have been determined at atmospheric pressure. The glass tube in which the condensation was effected was surrounded by a bath of liquefied ethylene, which could be caused to boil by reduction of its pressure, and, by use of a specially constructed air-pump, was reduced in temperature to − 150°. When this point was reached, the gas to be liquefied was admitted into the tube from a Natterer cylinder containing the gas at about 40–60 atmospheres pressure, and was readily liquefied. A hydrogen thermometer was used to determine the temperature of the liquid, and the boiling-point of methane at atmospheric pressure was found to be – 164° C., that of oxygen – 181°·4, nitrogen – 194°·4, carbon monoxide – 190°, and nitric oxide – 153°·6. The melting-point of carbon monoxide was also determined to be – 207°, and that of nitrogen as low as – 214°. M. Olszewski's nearest approach to absolute zero was – 225° for solid nitrogen. The density of methane at 736 mm. and – 164° was found to be 0·415, that of oxygen at 743 mm. and – 181°·4 was 1·124, while that of nitrogen at 741 mm. and – 194°·4 was found to be 0·885. The densities were determined by reading off the position of the liquid meniscus in the tube, volatilising a portion by means of an aspirator, and again reading off the height of the column, the volume of the volatilised portion being measured by the amount of water running out of the aspirator. At the fifth experiment with nitrogen, the tube, which had survived two years' experiments, burst, and destroyed the apparatus, so that the densities of carbon monoxide and nitric oxide must be left for future experiments.

ON Saturday next, and the two following Saturdays, Dr. R. von Lendenfeld will deliver a course of lectures at the Royal Institution on recent scientific researches in Australasia.

ON the 4th inst. the first meeting of the Sanitary Legislation Conference was held in the rooms of the Sanitary Assurance Association. The following resolutions were passed: (1) that the sanitary registration of all buildings is desirable in the interest of the public health; (2) that it is desirable that the law should forbid any building being used for public or semi-public purposes, unless and until the arrangements for the water-supply, drainage, and ventilation of such building have been certified as satisfactory by some properly-qualified person; and (3) that the provision of a public sanitary register for the voluntary registration of private houses would be instrumental in promoting sanitary improvement.

AN important topographical and geological Expedition has been organised by the Canadian Government for the exploration of the country watered by the River Yukon. According to Lieut. Schwalk, who went over much of the ground for the U.S. Government in 1883, this river is over 2000 miles in length, and it is believed that in many districts there are valuable deposits of gold. The Expedition will start from Victoria, British Columbia, early in May. The part of the work relating to geology and natural history will be conducted by Dr. Dawson, Assistant-Director of the Canadian Geological Survey; and under him Mr. W. Ogilvy will take charge of the topographical work, and make an accurate survey and measurement of as much of the Yukon as lies within British territory.

IT has been determined to transfer the Observatory of Rio de Janeiro to Santa Cruz, nearly on the same parallel, and a little more to the west. The Observatory is of considerable importance, owing to its position, being nearly on the Tropic of Capricorn, and it has recently been greatly improved by the present Director, Sr. Cruls. It is stated in the *Bollettino mensuale* of the Italian Meteorological Society, that from January of the present year the Observatory will commence the publication of a monthly Bulletin containing *inter alia* the meteorological observations made at fifteen stations in Brazil. Hitherto observations from that country have been very scarce indeed.

AFTER the first International Ornithographical Congress at Vienna in 1884, numerous stations for observing the habits of birds were organised all over the world. Dr. A. B. Meyer, the Director of the Zoological Museum at Dresden, was appointed Director for the erection of all such stations in Saxony. This gentleman, together with Dr. F. Helm, of Arnoldsgrün, has just published the first Annual Summary for the year 1885. It contains the results of about forty-eight series of observations from thirty-six stations, and articles on 180 species of birds.

WE have received four numbers of the "Encyclopædie der Wissenschaften," edited by various eminent German men of science, and issued by Trewendt of Breslau. One of these numbers concludes an elaborate dictionary of mineralogy, geology, and palæontology. Two others form part of an equally elaborate dictionary of chemistry, and the remaining number contains some sections of a treatise on botany.

THE Religious Tract Society are about to publish "Pioneering in New Guinea," by the Rev. James Chalmers, who has lived and travelled in New Guinea during the last eight years. A special chapter contains answers given by natives to 115 questions carefully drawn up by Mr. Chalmers.

"A LIST OF BRITISH BIRDS," revised by Mr. Howard Saunders, will be found of much service both for the labelling of specimens and for reference. It has just been issued by Messrs. Gurney and Jackson.

EARTHQUAKES on April 1, 2, 3, and 4 are reported from Aden. No damage was done.

WE hear that Mr. Murray has resigned the post of Librarian and Curator to the Karachi Museum. During his tenure of office he has written several hand-books on the zoology of Sind, and his Catalogue of the vertebrate fauna of that province is a valuable epitome of the subject. He will be succeeded by Mr. W. D. Cumming, who was for some time stationed at Fao, in the Persian Gulf. While there Mr. Cumming devoted himself with much energy to the study of the avifauna of the neighbourhood, and sent several interesting collections to England, where they have been described by Mr. Bowdler Sharpe. The collections proved to be one of the most important acquisitions of the British Museum during the year 1886.

LARGE cases, showing the nests of the Heron, Hen-harrier, Starling, Sand-Martin, and Common Tern, have been lately added to the Natural History Museum. Prof. Flower has also placed in the great hall a large case illustrating the principal breeds of domestic pigeons derived by man's selection from the common blue Rock-pigeon (*Columba livia*). Popular guides to most of the departments have recently been published by the Trustees, and the Index Museum in the great hall bids fair to supply the student with a complete introduction to the study of zoology and botany. In face of the energetic labours of the staff of this Museum to render the collections under their charge educational for the masses, it is satisfactory to learn that several members of Parliament have announced their intention of questioning the wisdom of reducing the grant to the British Museum, as has been done this year in deference to the rage for economy at present in vogue.

PROF. BARBOZA DU BOCAGE has recently described a Sun-bird and a Grass-warbler from the Island of St. Thomas as *Cinnyris newtonii* and *Prinia molleri*. Zoologists will welcome the return of Prof. Bocage from the realms of politics back to the charge of the Lisbon Museum, which, under his care, rose to a position of first-rate importance.

VOLUME I. of the Journal of the Science College of the Imperial University, Japan, which has been recently published, contains a valuable paper by Mr. Sekei Sekiya, Professor of Seismology in the University, on the comparison of earthquake records given at the same station by different seismographs, the comparison being made as a test of the accuracy of the instruments. Two recent earthquakes are discussed, each of which was recorded in duplicate at the Tokio Observatory, by two somewhat different forms of Ewing's horizontal pendulum seismograph, and the autographic records are reproduced in the paper. Prof. Sekiya compares the corresponding motions as recorded by different instruments, and remarks that when the records are gone through, wave by wave, the corresponding pointers are found to have drawn waves of exactly the same amplitude and period, and even the irregular minor ripples which are superposed on the principal undulations are reproduced faithfully by both. He concludes that this exact coincidence proves conclusively the trustworthiness of the horizontal pendulum seismograph. The diagrams reproduced in the Journal also show the vertical motion of the ground, as recorded by Ewing's vertical motion seismograph. This motion, the author points out, is much less in amplitude than the horizontal motion (usually from $\frac{1}{3}$ to $\frac{1}{4}$), and its average period is only about half that of the horizontal motion. The three components of motion, when combined, give a resultant form of extraordinary complexity for the path pursued by particles on the surface of the ground during an earthquake shock.

THE Association Scientifique de France has discontinued the publication of its weekly Bulletin, and will issue, instead, a *Compte rendu* of the Conferences of the Association in half-yearly volumes. A few advance parts will be published fortnightly, for the use of such of the members as may desire to have them. The Bulletin has been published since 1864.

MR. JAMES WILD, Geographer to the Queen, died at his London residence, at the age of seventy four, on the 17th inst. He was educated at Woolwich for the army, but afterwards devoted himself to the production of scientific and educational works. He soon became a member of various scientific Societies, and his maps and geographical works secured for him the position of Geographer to the Queen. For a good many years he had a seat in Parliament. After his retirement from political life he represented the Ward of Cornhill in the Common Council, and he took a leading part in directing the attention of the Clothworkers' Company, of which he was a member, to the subject of technical education. It was mainly through his efforts that the technical schools of Bristol, Manchester, and Leeds were erected. Among the many honours conferred upon him was the gold medal for scientific merit, granted by the present German Emperor as King of Prussia.

IN a paper entitled "Field Notes from Afghanistan," printed in the new number of Records of the Geological Survey of India, Mr. C. L. Griesbach gives an account of instances of recent glacial action observed by him when crossing the Hindu Kúsh by the Chahárdar Pass in October 1886. The road which leads from Chápdarra camping-ground on the north side of the Hindu Kúsh to the top of the pass ascends a narrow straight valley, bounded on each side by steep cliffs, some of them crowned with perpetual snow. The bottom of the valley itself is greatly choked and partially filled with debris, which might be simply the detritus from the hill-sides. Large cones and fans of fragmentary material descend from each small ravine on both sides. So far only the configuration of the valley, its nearly straight course and absence of larger side streams, would suggest the former presence of glaciers. But on reaching an elevation of 12,000 feet, one suddenly comes to a huge mass of debris, which closely resembles the recent accumulations near the lower end of a glacier. Large blocks, some of them of immense dimensions, are loosely mingled with angular fragments of every size, and the whole is arranged like a dam across the valley. The hill-sides (gneiss) are polished and grooved, and the blackened surfaces glisten and shine in the distance like metal. All the larger blocks show extensive grooving and deep ice-scratches on their polished sides. This mass of debris lies at the base of a terrace filling the valley. The former glacier, of which this is the end moraine, was on the upper and raised portion of the valley. The latter bears the remarkable appearance of an ice-worn trough; it is wider than the valley below, and its base is now partially filled by finer debris, through which a small stream winds its way amidst a series of swampy pools. It is within the area of perpetual snow, and the latter with frozen patches of ice lies on the hill-sides and in sheltered depressions. The valley looks as if the glacier had only quite recently left it. Moraines and glacial silt still lie as they were deposited. The head and catchment area of the valley close to the top of the pass (14,100 feet) is still rather thickly covered with frozen snow. Near the head of a narrow valley leading from the Chahárdar Pass to the Deh-i-Tang, at an elevation of 12,050 feet above sea-level, several small ravines join. Mr. Griesbach noticed that three of these ravines were still filled with glaciers. Although they were very small, the moraine accumulations near their lower ends were enormous.

IN a highly important and interesting paper on the structure of the Nostochineæ, contained in the first volume of the new Italian botanical journal *Malpighia*, Prof. A. Borzi, of Messina, states the very interesting fact that, in *Nostoc ellipsosporum* and other species of the same genus, a distinct communication can be detected between adjacent cells. If the cell is an intercalary one, it has two pores at opposite poles; if apical, only one; and through these pores pass very delicate threads of a substance which sometimes gives the reactions of protoplasm, sometimes of cyanophycin, the substance of which, according to Borzi, both the cell-contents and the investing gelatinous sheath of the Nostocaceæ are composed. This intercommunication between the cells is always interrupted in the formation of heterocysts. During the transformation of ordinary cells into heterocysts, the walls become thicker, the gelatinous substance of which they are composed collecting especially round the pores through which the strands pass, and eventually completely closing them up. In this way is formed a short conical projection pointing towards the interior of the heterocyst. In the vegetative cells of the filament, that is, those which are not destined to become heterocysts, the connecting threads appear always to consist of protoplasm. In the hormogones this connexion between adjacent cells is especially evident. In addition to several species of *Nostoc*, Prof. Borzi has observed this interesting phenomenon in several of the other families of Nostochineæ or filamentous Cyanophyceæ, viz. in the Scytonemaceæ, Stigonemaceæ, and Rivulariaceæ.

PROF. D. KIKUCHI, of Tokio, who graduated at Cambridge in 1877, is editing, at the request of the Education Department of the Japanese Government, text-books of geometry and algebra, those in use at present being very unsatisfactory. He has already translated and published the syllabus of plane geometry drawn up by the Association for the Improvement of Geometrical Teaching, and has also done the same for Clifford's "Common Sense of the Exact Sciences." His principal course of lectures—a two years' one—is on dynamics, commencing with statics, and including sound and liquid waves.

WITH reference to Mr. Hooper's paper on *Gymnema sylvestre*, printed by us last week, Mr. J. C. Shenstone writes to us that the peculiar properties of the plant were described in a communication to the Linnean Society, December 7, 1847, by Capt. Edgeworth. The plant was pointed out to him by the natives, who were aware of its peculiarity. "No doubt," says Mr. Shenstone, "this is the Mr. Edgeworth alluded to by Mr. Hooper in his paper as having first discovered the property of the plant, but a reference to the original communication may interest some of your readers."

AN experimental passenger-train, lighted throughout by electricity, and heated by steam from the engine, is now running between New York and Boston. Each car is illuminated by eighteen 16-candle glow-lamps, the current being derived from storage-batteries beneath the floor-timbers, charged for ten hours by dynamos. Both light and heat are said to be ample, and *Science* believes that danger from fire, in case of accident to the train, is much lessened, if not almost wholly done away with

MACHINERY for winding silk from cocoons was lately set up at Washington by the Department of Agriculture. Much interest is manifested in the experiments, and the demand for copies of the Bulletin on Silkworm Culture is so great that it has been necessary to issue seven or eight editions. According to officials of the Department of Agriculture, the requests for silkworm eggs have never been so numerous since the Department began their distribution. It is expected, therefore, that large quantities of American-grown silk will be placed upon the market this year.

WHEN crossing the Atlantic, Prof. Dennis, of New York, recently made some observations to test the purity of the ocean-air. He had previously prepared capsules of sterilised gelatine. One which was exposed in a state-room on the main deck of the steamer developed five hundred points of infection in eighteen hours; one exposed in the cabin on the main deck developed only five or six points in ten days; a third, hung over the bow of the ship for ten days, remained uncontaminated.

MR. V. G. EATON, writing to the *Popular Science Monthly*, says that in most of the eastern cities of the Unites States fully 30 per cent. of the men over thirty years of age show unmistakable signs of baldness, while nearly 20 per cent. have spots on their heads that are not only bald, but polished with the gloss that is supposed to belong to extreme old age alone He has been in most of the churches and theatres in all the large eastern cities, as well as in Chicago, St. Louis, and other places of the West, and has verified his assertion by actual count. He has found that bald-headed men are most plentiful in New York and Boston, and that after these cities come Philadelphia, Washington, and the western towns. The following are a few of his observations taken in Boston:—Trinity Church · 243 men, 71 actually bald, 46 indications of baldness. King's Chapel : 86 men; 38 actually bald, 14 indications of baldness. Hollis Street Theatre, orchestra at performance of the "Mikado" · 63 men; 27 actually bald, 10 indications. Boston Theatre, Judic: 126 men; 51 actually bald, 43 indications.

THE additions to the Zoological Society's Gardens during the past week include two Polar Bears (*Ursus maritimus*), from the Polar Regions, presented by Mr. Joseph Monteith; two Brown-throated Conures (*Conurus aruginosus*), from South America, presented by Lieut General Newton; a Ring Dove (*Columba palumbarius*), a Turtle Dove (*Turtur communis*), British, presented by Mr. C. L. Sutherland, F.Z S.; a Secretary Vulture (*Serpentarius reptilivorus*), from South Africa, presented by Mr. J. Newbury; a White-tailed Buzzard (*Buteo albicaudatus*), from America, presented by Mr. John Lloyd; two Common Gulls (*Larus canus*), British, presented by Mr. J. A. Cotton; two —— Ducks (——) from the Falkland Isles, presented by Mr. F. E. Cobb, C.M.Z.S.; two Viscachas (*Lagostomus trichodactylus*), born in the Gardens.

OUR ASTRONOMICAL COLUMN

THE U.S. NAVAL OBSERVATORY.—We learn from *Science*, vol. ix No. 217, that the new Naval Observatory, for which Congress appropriated 400,000 dollars several years ago, is to be built forthwith. Mr. R. M Hunt, of New York, has been appointed architect of the building, and operations will shortly begin.

RESEARCHES ON THE SUN'S DIAMETER.—Prof. Di Legge, of the Campidoglio Observatory, Rome, has published in *Atti della R. Accademia dei Lincei*, ser. 4, vol. i., a discussion of the meridian transit observations of the sun's diameter taken at the Observatory during the years 1874–83. From May 1876 the observations were made by projecting the sun's image on a screen, so that two or more persons could observe simultaneously, and thus determine their "personal equations" from observations made under precisely similar circumstances. Altogether, 5796 transits were observed on 2213 days, giving an average of 221 days per annum The mean resulting horizontal semi-diameters of the sun, collected in biennial groups, show a progressive diminution, which, taking into consideration Auwers' researches on the subject (NATURE, vol. xxxv. p. 496), are most probably due to change in the habits of the observers, as the table of mean annual personal equations given by Prof. Di Legge would also lead us to infer. The mean values of the horizontal semi-diameter at mean distance found from each observer's transits are respectively as follows:—Di Legge, 961″·329 ± 0″·011; Respighi, 960″·760 ± 0″·013; Giacomelli, 961″·307 ± 0″·012; and Prosperi, 961″·356 ± 0″·014; the combined mean value being 961″·188.

ASTRONOMICAL PHENOMENA FOR THE WEEK 1887 APRIL 24–30

(FOR the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is here employed.)

At Greenwich on April 24.

Sun rises, 4h. 48m.; souths, 11h. 58m. 5·6s.; sets, 19h. 8m.; decl. on meridian, 12° 51′ N.: Sidereal Time at Sunset, 9h. 18m.

Moon (at First Quarter on April 30) rises, 5h. 48m.; souths, 12h. 55m.; sets, 20h. 14m.; decl. on meridian, 12° 11′ N.

Planet	Rises h. m.	Souths h. m.	Sets h. m.	Decl. on meridian ° ′
Mercury	4 17	10 23	16 29	0 20 N.
Venus	6 1	14 13	22 25	22 50 N.
Mars	4 50	11 59	19 8	12 37 N.
Jupiter	18 34	23 45	4 56*	10 17 S.
Saturn	8 54	17 3	1 12*	22 24 N.

* Indicates that the setting is that of the following morning.

GEOGRAPHICAL NOTES

The new volume (xi.) of the *Geographische Jahrbuch*, edited by Prof. Hermann Wagner, begins a new series, and assumes a new form. It has been elongated from the small square form with which we have been familiar, into a respectable octavo, containing about 500 pages. Moreover the present volume is entirely devoted to what in former years was only a section: an account of progress in the various departments into which scientific geography is divided. The next volume will no doubt contain memoirs on various subjects of geographical interest. The subject of physical geography (or rather geophysics) is treated by Dr. Hergesell and Dr. Rudolph. Prof. Toula deals with the investigations of the last four years in the geognostic structure of the earth's surface in all parts of the world. The progress of oceanography is of course dealt with by the great authority on the subject, Dr. O. Krummel, while Dr. Hann does a similar service for geographical meteorology, or climate. Botanical geography is treated by Dr. Oscar Drude, and zoological geography by Dr. L. K. Schmarda. Dr. G. Gerland gives the results of research in ethnology during 1884–86 in the various quarters of the globe. Under Dr. Wagner's sole editorship the *Jahrbuch* is becoming more valuable than ever as a book of reference in scientific geography.

The Rev. George Grenfell, the explorer of the Mobangi and other important tributaries of the Congo, has arrived in London. Unfortunately his health is by no means satisfactory, and it will be necessary for him to rest for some time, therefore his appearance at the Royal Geographical Society must be delayed. He has brought home with him his original maps, which are admirable specimens of such work. They are on a scale of about 5 inches to a mile, and are evidently plotted with the greatest care; his work is therefore likely to take a high place. Dr. Lenz, who has arrived in Vienna, it is hoped will be in London at the end of this month, and as Dr. Junker may be here about the same time, it is just possible that both these eminent explorers may appear together at the first meeting of the Geographical Society in May.

Under Colonel Woodthorpe, the work of surveying our new Burmese territory is proceeding apace. Up to the end of January the out-turn of work amounted to 800 square miles on the ¼-inch, and 260 miles on the ⅛-inch scale.

The narrative of Baron Nordenskjöld's memorable journey into the interior of Greenland in 1883, is now appearing in instalments in the German journal *Globus*, profusely illustrated.

Two Expeditions are being sent out by the Russian Geographical Society this year: one, under J. P. Kusnetzow, to investigate the flora of the Northern Urals; and another, under Prince Massalsky, to continue his Transcaucasian researches, which include both botany and ethnography.

VALENCY AND RESIDUAL AFFINITY[1]

II.

Metallic Conduction.—I do not propose in any way to discuss metallic conduction, but merely to call attention to some of the analogies between it and electrolytic conduction.

It is conceivable, and it would appear probable from the fairly regular manner in which the electrical resistance of most pure metals decreases as the temperature falls, the coefficients of change being practically very nearly the same in all cases, that the increase in resistance as temperature rises is mainly due to the increase in molecular inter-distances. As a rule, resistance increases on the passage of a metal from the solid to the liquid state, but there are noteworthy exceptions from which it would appear probable that even in pure metals conductivity to some extent depends on molecular composition: thus the conductivity of bismuth increases at the moment of fusion from 0·43 to 0·73 of that of mercury at 31°, and that of antimony from 0·59 to 0·84 (L. de la Rive, *Comt. rend.*, 1863, lvii., p. 691); it is well known that bismuth contracts considerably on fusion, and this is probably also the case with antimony. Again, according to Bouty and Cailletet (*ibid.*, 1885, c., p. 1188), the resistance of mercury decreases at the point of solidification in the ratio 4·08 . 1; this is a remarkable increase in conductivity, and it is difficult to believe that it is wholly due to mere contraction of volume.

That the behaviour of alloys is worthy of far more attention than it has hitherto received appears most clearly from the few data at disposal. I would specially call attention to the curve given by Prof. Lodge as representing the specific conductivities of the copper-tin alloys (Phys. Soc. Proc., 1879–80, iii., p. 158). The general resemblance of this curve to that given by F. Kohlrausch for mixtures of sulphuric acid and water appears to me to be in the highest degree suggestive.

Valency—Chemical Change.—Notwithstanding the fierce controversy which has been waged between the advocates of the doctrine of fixed valency, our views on the subject are still in an unfortunate degree unsatisfactory and indefinite. Even those—and they probably form a large majority—who regard valency as a variable, dependent both upon the nature of the associated radicles and the conditions—especially as to temperature,—under which these are placed, often hesitate to attribute a valency sufficiently high to account for every case of combination; in fact, both parties agree in distinguishing "atomic" from "molecular" compounds, and differ only as to where the line shall be drawn.

It is difficult to over-estimate the importance of the theory of valency: its application has led to an enormous extension of our knowledge of carbon compounds especially, and it has furnished us with a simple and consistent system of classifying the mighty host of these bodies; but, on the other hand, it may be questioned whether it has not led us away from the search into the nature of chemical change, and even if the introduction of the terms saturated and unsaturated has not had a directly pernicious effect. The almost universal disregard of molecular composition as an important factor in chemical change in the case of solids and liquids, and the popular tendency to overlook the fact that our formulæ of such bodies are purely empirical expressions, has undoubtedly exercised a prejudicial influence.

No known compounds *are saturated*: if any were, such would be incapable, I imagine, of directly taking part in any interaction, and in their case decomposition would necessarily be a precedent change. The paraffins are apparently, of all bodies, the most inert and the most nearly saturated,[1] and next to them comes hydrogen—the unsaturated character of which is displayed in interactions such as occur at atmospheric temperatures between it and platinum and palladium, and when it displaces silver from silver nitrate or certain of the platinum metals from their salts. One of the most striking instances, perhaps, of popular error in this respect is water, which is always regarded as a saturated compound, although its entire behaviour, and especially its physical properties, characterise the molecule H_2O, I think, as that of an eminently unsaturated compound: I fail to see how, otherwise, we are to explain the high surface-tension and high specific heat of liquid water, its high heat of vaporisation, and its imperfectly gaseous behaviour up to temperatures considerably above its boiling-point, let alone its great solvent power and its tendency to form hydrates with a multitude of compounds—*especially oxygenated* compounds, be it added.

The theory was brought most prominently under the notice of chemists by Helmholtz in the last Faraday Lecture, that electricity, like matter, is, as it were, atomic, and that each unit of affinity or valency in our compounds is associated with an equivalent of electricity—positive or negative; that the atoms cling to their electric charges, and that these charges cling to each other. Thus barely stated, this theory does not appear to take into account the fact that the *fundamental* molecules, even of so-called atomic compounds, *are never saturated*, but more or less readily unite with other molecules to form molecular compounds—molecular aggregates; and unless the application of the theory to explain the existence of such compounds can be made clear, chemists must, I think, decline to accept it. The impression which the facts make upon the mind of the chemist certainly is (1) that no two different atoms have equivalent affinities; and (2) that affinity is a variable depending on the nature of the associated elements: but, owing to the recognised complexity of nearly all cases of chemical change, it is difficult to draw any very definite conclusion on this point.

If, however, the nature and properties of so-called molecular compounds generally be considered, and if an attempt be made to form any conception of their constitution, one striking fact is noticeable, viz. that the *metals* in them apparently retain the properties which they exhibited in the parent atomic compounds. Everyone knows the marked difference in properties of ferrous as contrasted with ferric salts: they differ not only in chemical behaviour, but also in their physical properties, and are readily distinguishable by their colour. The properties of the ferrous molecular compounds, however, are those of the simple ferrous compounds: ferrous potassium chloride, for example, $Fe_2Cl_4 . Cl_2K_2$, is a green salt much like ferrous sulphate. Facts such as these have led me to suggest that in such cases the formation of the molecular compound is due to the attraction of the negative element of the one "atomic" compound by the negative element of the other, the metal having no influence except that the amount of affinity of which the negative element is possessed depends on the nature of the metal with which it is associated. It would in fact appear that hydrogen and the metals generally may be regarded as the analogues of the C_nH_{2n+1} and C_nH_{2n-7} hydrocarbon radicles, and that their compounds with negative elements may be likened to unsaturated hydrocarbons of the form $C_nH_{2n+1} . CH . CH_2$. We know that whenever such a compound enters into combination, the C_nH_{2n+1} radicle takes no part in the change, combination of whatever kind being effected by means of the unsaturated radicle, $CH . CH_2$, with which it is associated. I do not mean to contend that the metals are fully neutralised in their compounds, but merely that as a rule they behave as though they were saturated, just as do the C_nH_{2n-7} radicles derived from the benzenes. There can be little doubt that an absolute distinction must be drawn between hydrogen and the metals on the one hand, and the non-metals on the other. Regarding the facts in the light of our knowledge of carbon compounds, it is difficult to resist the conclusion that the differences observed are due to differences in structure of the stuffs of which the elements as we know them are composed, the which differences condition perhaps a different distribution of the electric charge or its equivalent, in the case of each element.

---

[1] Revision and extension of a paper by Prof. H. E. Armstrong, F.R.S., communicated to the Royal Society last year. Continued from p. 572.

[1] It is probably more correct to place nitrogen first in the list, as being the most inert substance known.

ADDENDUM, *April* 1887.—I will now venture to call attention to the points which after a year's further consideration of the subject appear to me of special importance.

We are as far as we ever were from being able to define a "simple electrolyte" in the chemical sense—that is to say, to define the class or classes of compounds to which simple electrolytes belong. The investigation of the electrical behaviour of *pure* compounds is therefore of the highest importance; it is essential, however, to bear in mind that not only must pure compounds be studied, but scrupulous care must be taken to guard against a possible decomposition of the substance under examination, either by heat alone, or by contact with the electrodes or the containing vessel. I believe that the conclusions which Clark based on his most interesting observations on the electrolysis of mercuric salts are vitiated by some such effect having been overlooked. The experimental difficulties surrounding the problem are therefore very great; and the more hopeful method of attacking it in many cases would appear to be that adopted in Kohlrausch's experiments on the specific resistance of water: in other words, to determine the influence of impurities.

A similar problem relates to the possibility of basing a definition of a non-metal as distinct from a metal on electrical properties. It is well known that no consistent definition can be given, and that we are at present obliged to base our division of the elements into metals and non-metals on general considerations. Now, although metals differ enormously in specific resistance, the metals as a class oppose a comparatively feeble resistance to the passage of electricity, and moreover resistance always increases as the temperature of a metal rises; it is therefore noteworthy that not only is the specific resistance of non-metals, such as carbon, phosphorus, selenium and sulphur, enormously great in comparison with that of metals, but that it diminishes as temperature rises: non-metals therefore behave in this respect as electrolytes, and as no special precautions have hitherto been taken to obtain pure non-metals for the purpose it is well worth while to ascertain if the specific resistance offered by non-metals be not the greater the nearer the approximation to purity.

To determine the valency or atom-fixing power of an element, according to present views, it is necessary to determine the number of atoms which can enter into direct association with an atom of the element considered; and this necessarily involves a discussion of the nature of "atomic" as distinct from "molecular" compounds. The electrical hypothesis that an atom of unit valency carries unit charge, a dyad two such charges, a triad three, involves the more specific determination of the number of charges which are associated with any particular atom; but, again, on this hypothesis we have to determine whether any real distinction can be drawn between atomic and molecular compounds, and whether an atom having, say, unit charge, has the power of combining with more than a single atom. My own view certainly is that atomic and molecular compounds are specifically distinct; and that in the latter the number of atoms associated with what may be regarded as the grouping element or elements in the compound is in excess of the number of unit charges which the particular element or elements of necessity carry. Taking nitrogen as an example, it appears to me that the whole of the evidence to be derived from the study of nitrogen compounds is compatible with the assumption that nitrogen carries at most three charges: that it is a triad, in fact; and I am inclined to regard the ammonium compounds of the type $NH_3 . HX^1$ as molecular compounds in which the residual affinities of N and X^1 serve to unite H_3N with X^1H. The more I study the question the more I incline to the belief that sooner or later we must accept Kekulé's ruling, unfashionable as this has become of late years.

The foregoing may appear to many to be but a restatement of the tenets of the advocates of the doctrine of fixed valency. It appears to me, however, that in the hypothesis of a definite unit charge—in other words, of a definite unit valency—we have a conception which for the first time enables us to frame a consistent doctrine of valency: a given atom may be assumed to carry under all circumstances a certain definite charge, and the problem which the chemist has to determine is, firstly, the number of unit charges associated with any particular atom, and, secondly, the manner in which the charge is, as it were, distributed when the atom is brought into association with other atoms. The following illustration will perhaps serve to make my meaning clear. Let unit charge or unit valency be regarded as a unit "line of affinity" passing through the atom, and let it be supposed that the atom moves upon this line of affinity with a degree of freedom depending on its nature; then it may be supposed that combination between two atoms consists in the overlapping of the lines of affinity. If each atom move out to the end of its line of affinity, no part of the line will overhang; the molecule will consequently be saturated; there will be no residual affinity. On this view the stability of a molecule will depend on the extent to which the lines of affinity of the constituent atoms *overlap*, and its tendency to associate with other molecules will depend on the extent to which the lines of affinity of the constituent atoms *overhang*. For example, it may be supposed that in ordinary chlorine the two atoms of which the molecule consists have moved out near to the end of the lines of affinity, so that there is but little overhang: the molecule is therefore of considerable stability, but forms unstable combinations with other molecules; in iodine, on the other hand, it may be supposed that the atoms are closer together, the lines of affinity overlapping less than those of chlorine; consequently the molecule is less stable than that of chlorine, but may form more stable molecular compounds as the lines of affinity overhang to a greater extent than do those of chlorine. It is possible in this way to understand that an atom which carries but unit charge—a monad, in fact—may enter into association with two distinct atoms. Adhering to the above symbolic language, it may even be suggested that perhaps the difference between a non-metal and a metal may be that the structure of the non-metals is such that they move with difficulty upon their lines of affinity, and probably in a very limited number of directions, and with unequal freedom in different directions; and that the structure of metals is such that they move with comparative freedom upon their lines of affinity, in some cases even with complete freedom, and almost equally so in several directions.

Speculations such as these are of value only if they serve as a guide to further inquiry. I venture to put them forward in the hope of inducing chemists to devote more attention to the study of molecular compounds, for it is in this direction that we are likely to gather most important information as to the valency of elements other than carbon and hydrogen. Of late years such inquiries have been but rarely pursued, and no doubt they are less attractive than those which result in some new synthesis or the determination of the constitution of an organic product; but their future value will be great, and the number of workers is now so large that our sense of proportion demands that attention should no longer be directed almost exclusively to the study of carbon compounds.

There is one other problem to which I would direct attention—the study of liquid diffusion. No interpretation of the remarkable results obtained by Graham has yet been given, and they appear in many cases to be quite at variance with the results of chemical inquiries. But there is a striking parallelism to be observed between Graham's results and those obtained on determining the electrical conductivity of solutions. Applying the view which I hold regarding the electrolysis of composite electrolytes to liquid diffusion, it appears to me not improbable that diffusion may be to a large extent the outcome not so much of the proper motion of the molecules of the dissolved substance as of a propulsive action exercised by the molecules of the solvent. The molecules in a mass of water we know may be assumed to be moving in every direction and this being the case they would tend to carry other molecules along with them: the extent to which this action would take place would, however, largely depend on the attraction which exists between the molecules of water and those of the dissolved substance. From this point of view it appears of considerable importance to extend the study of liquid diffusion to dilute solutions. It may be added that this hypothesis would probably account for the behaviour of colloids, as these are known to be chemically neutral substances; in fact, they are compounds almost destitute of residual affinity.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

King's College, London.—Prof W. Grylls Adams, F.R.S., will deliver a course of lectures on Electro-Magnetism, Magneto-Electricity, the Testing of Motors and Dynamos, Electric Lighting, and Transmission of Power, during the present Term.

A course of practical work in Electrical Testing and Measurement with especial reference to Electrical Engineering will also be carried on under his direction in the Wheatstone Laboratory.

The lectures will be given once a week—on Mondays, at 2 p.m.,—and the Wheatstone Laboratory is open daily from 1 to 4, except on Saturdays.

SOCIETIES AND ACADEMIES

London

Royal Society, March 31.—"Note on the Development of Voltaic Electricity by Atmospheric Oxidation." By C. R. Alder Wright, D.Sc., F.R.S., Lecturer on Chemistry and Physics, and C. Thompson, F.C.S., Demonstrator of Chemistry, in St. Mary's Hospital Medical School.

Whilst investigating processes for the manufacture of cuprammonium hydroxide (now used commercially on a considerable scale) we noticed that if the air supply be greatly in deficiency relatively to the bulk of the copper, under certain conditions the solution is but little coloured, containing copper dissolved principally as cuprous, and not as cupric, oxide. This might, perhaps, be anticipated *a priori*, inasmuch as it is well known that blue cupric solution in ammonia, when digested with metallic copper in the absence of air, takes up a second equivalent of copper, becoming colourless cuprous solution; but further experiments seem to indicate that the production of cuprous oxide under the oxidising influence of a limited supply of air is the primary action, and not merely a secondary result.

When a sheet of copper is kept out of direct contact with air by being immersed in ammonia solution, oxidation of the metal is gradually effected by virtue of the dissolving of oxygen from the air at the surface of the fluid, and diffusion of the oxygen solution to the vicinity of the copper. This action is an extremely slow one if the copper be covered by some depth of fluid, and if the setting up of convection currents through heating or evaporation be prevented by keeping the vessel perfectly at rest and at an equable temperature, and well closed to prevent escape of ammonia; but if these precautions be neglected it goes on much more rapidly, and the liquid comparatively soon becomes blue; it can, however, be also materially accelerated by arranging horizontally on the surface of the fluid a plate of platinum or other electrically conducting material not chemically acted upon by the fluid, and connecting this by means of a wire, &c., with the copper plate. The upper conductor, or *aëration plate* as it may be conveniently termed, being simultaneously in contact with the atmosphere and fluid, attracts to its surface a film or aura of condensed gases, the oxygen of which becomes gradually transferred to the copper, a voltaic current circulating through the fluid and connecting wire. Cuprous, and not cupric, oxide thus results, dissolved in the ammonia solution in contact with the copper plate, the mechanism of the reaction being conveniently represented by the scheme—

$$\left\{\begin{array}{l} \text{Copper plate}\quad Cu_2 \mid OH_2 \mid OH_2 \mid O\ \text{Aeration plate,} \\ \\ \text{Copper plate} \mid Cu_2O \mid H_2O \mid H_2O \mid \text{Aëration plate,} \end{array}\right.$$

water being represented as the electrolyte for simplicity's sake. The air film on the aëration plate being constantly renewed by absorption from the atmosphere, the process goes on continuously as long as the two plates are connected together by the wire. This wire may be lengthened at will so as to make the current which passes through it whilst the action goes on relatively stronger or weaker according to the amount of resistance introduced into the circuit; and by including a galvanometer or silver voltameter in the circuit the ordinary phenomena due to the passage of currents are readily recognisable.

The maximum E.M.F. thus capable of development varies considerably with the strength of the ammoniacal solution, being the less the weaker the fluid; addition of common salt or of sal ammoniac to the liquid notably increases the E.M.F. and diminishes the internal resistance of the cell. Spongy platinum in a thin layer as the aëration plate gives higher values than thin platinum foil; the highest numbers thus obtained, using pretty concentrated ammoniacal brine, fell but little short of 0·8 volt; or somewhat less than the E.M.F. corresponding with the heat of formation of cuprous oxide,[1] since, according to Julius Thomsen, Cu_2O = 40,810 = about 0·88 volt.

It is obvious that this copper atmospheric oxidation cell has a close connexion with the "air-battery" described in 1873 by Gladstone and Tribe (Roy. Soc. Proc., vol. xxi. p. 247) in which what is virtually an "aëration plate," consisting of a tray full of crystals of silver is used, opposed to a copper plate immersed in a solution of copper nitrate. Cuprous oxide is formed in both cases, in virtue of the indirect combination brought about between the oxygen of the air and the copper: but there is this great difference between the two (apart from the cuprous oxide being deposited as such in Gladstone and Tribe's arrangement, and being kept in solution in ours), that in the one the cuprous oxide is formed *at the surface of the copper plate* itself, and in the other *at the surface of the aëration plate.* This essential difference is embodied in the above depicted scheme as compared with the following one which represents the action in Gladstone and Tribe's cell:—

$$\left\{\begin{array}{l} \text{Silver} + O \left| \begin{matrix} Cu(NO_3)_2 \\ Cu(NO_3)_2 \end{matrix} \right| \begin{matrix} Cu(NO_3)_2 \\ Cu(NO_3)_2 \end{matrix} \left| \begin{matrix} Cu \\ Cu \end{matrix} \right\} \text{Copper.} \\ \\ \text{Silver} \left| O \begin{matrix} Cu \\ Cu \end{matrix} \right| \begin{matrix} (NO_3)_2Cu \\ (NO_3)_2Cu \end{matrix} \left| \begin{matrix} (NO_3)_2Cu \\ (NO_3)_2Cu \end{matrix} \right| \text{Copper.} \end{array}\right.$$

One result of this difference is that the surface of the aëration plate in the ammonia cell is kept constantly the same, whereas in the nitrate cell it is continually changing its character through deposition of solid cuprous oxide on the silver: in consequence of this deposition, whilst the E.M.F. of the ammonia cell, *cæteris paribus*, is constant, that of the nitrate cell is continually varying. Gladstone and Tribe, moreover, only obtained an E.M.F. of $\frac{1}{10}$ to $\frac{1}{7}$ of a Daniell, or about 0·104 to 0·143 volt, even under the most favourable conditions, viz. when the cell was connected with an electrometer; whilst four or five times this amount is indicated by the cells examined by us.

Following up the ideas suggested by the above observations, we are making a number of experiments with a variety of analogous combinations, in which atmospheric oxidation constitutes the essential chemical action taking place; by varying the nature of the aëration plates, the metals dissolved, and the liquids employed (as also by substituting other gases, *e.g.* chlorine, for air), a large number of combinations are obviously obtainable. Some of those which we have so far examined present points of considerable interest, the oxidising action exerted under favourable conditions being strongly marked: so much so that certain metals, *e.g.* mercury and silver, not ordinarily prone to atmospheric oxidation, can under suitable conditions be gradually oxidised and dissolved in appropriate liquids, just as the copper is dissolved in the ammonia in the cell above described; these actions, moreover, being accompanied by the development of currents of strength sufficient to cause measurable amounts of electrolytic decomposition outside the cell, *e.g.* in a silver voltameter.

---

[1] The actual chemical change going on in the cell is the synthesis of cuproso-ammonium hydroxide, so that the (unknown) heat of solution of cuprous oxide in ammonia should be added to this to obtain the total heat development.

"Action of Caffein and Theine upon Voluntary Muscle." By T. Lauder Brunton, M.D., F.R.S., and J. Theodore Cash, M.D.

Caffein and theine both cause rigor in the voluntary muscles of frogs (*Rana temporaria*). The action is, however, very variable, the rigor being sometimes exceedingly well marked, and at other times not observable. Theine seems to be rather more powerful than caffein, but the quantitative difference between them is slight. There is, however, a marked qualitative difference between them, inasmuch as theine tends to produce rhythmical contractions in the muscle. A variation is observed in the action of the alkaloids on the different muscles of the same frog.

The addition of lactic acid to a solution of theine or caffein causes the rigor to appear sooner, develop more rapidly, and attain a greater maximum, and a somewhat similar effect is produced by calcium chloride. Potash retards and diminishes the action of theine or caffein. One phenomenon which seems deserving of attention is the rhythmic contraction of the muscle produced by theine. This rhythm is so slow that it would escape attention unless a very low rate of speed were used in the recording apparatus; it is sometimes as slow as from three to about one contraction per hour; it may continue for twenty hours. In one instance we observed the remarkable phenomenon to which we have given the name of pseudo-rigor; in this experiment the application of the theine was followed by slight relaxation of the muscle, to this succeeded an equal contraction, and then followed great relaxation below the normal, so great indeed that the negative curve below the abscissa strongly resembled the positive curve of contraction due to rigor in most other experiments.[1]

"Contributions to our Knowledge of the Connexion between Chemical Constitution and Physiological Action. Preliminary Communication on the Action of certain Aromatic Bodies." By T. Lauder Brunton, M.D., F.R.S., and J. Theodore Cash, M.D.

The distinctive action of the lower members of the fatty series is their stimulant and anæsthetic action on the nerve-centres.

The members of the aromatic series also affect the nervous system, but they appear to affect the motor centres more than the sensory, so that instead of producing anæsthesia, like the members of the fatty series, they tend rather to produce tremor, convulsions, and paralysis. Benzene, chlorobenzene, bromobenzene, and iodobenzene are all somewhat similar in their action on frogs; the halogen radicals not modifying the action of the benzene to such an extent as they do in the case of ammonium salts. The voluntary muscles are weakened by them, and there is a slight tendency to paralysis of the motor nerves; but the action is chiefly exerted upon the brain and spinal cord. The brain is first affected, as shown by general lethargy and disinclination to move. Next the cord is affected; motions are imperfectly performed, and there is a tendency to general tremor on movement resembling that observed in disseminated sclerosis; sometimes, however, the tremor is observed independently of movement.

The addition of hydroxyl to the benzene nucleus intensifies the convulsant action, so that oxybenzene (carbolic acid) and dioxybenzene cause convulsions in frogs, and trioxybenzene causes jerkings, though of a slighter character.

Zoological Society, April 5.—Prof. W. H. Flower, F.R.S., President, in the chair.—The Secretary read a report on the additions that had been made to the Society's menagerie during the month of March 1887.—Mr. F. Day exhibited and made remarks on a specimen of a Mediterranean fish (*Scorpæna scrofa*), taken by a trawler off Brixham early in March last, and new to the British fauna.—Mr. J. H. Leech exhibited some specimens of new butterflies from Japan and Corea, and gave a short account of his recent journeys to those countries in quest of Lepidoptera.—The Secretary read a letter addressed to him by the Rev. G. H. R. Fisk, of the Cape Colony, respecting the killing and eating, by a shrew, of a young venomous snake (*Sepedon hæmachates*).—Prof. Flower, F.R.S., communicated, on behalf of Messrs. John H. Scott and T. Jeffery Parker, of the University of Otago, N.Z., a paper containing an account of a specimen of a young female *Ziphius*, which was cast ashore alive at Warrington, north of Dunedin, New Zealand, in November 1884.—Mr. Richard S. Wray read a paper on the morphology of the wings of birds, in which a description was given of a typical wing, and the main modifications which are found in other forms of wings were pointed out. One of the principal points adverted to was the absence, in nearly half the class of birds, of the fifth cubital remex, its coverts *only being* developed. The peculiar structure of the wings in the Ratitæ and the *Sphenisci* was also commented upon.—A communication was read from the Rev. H. S. Gorham, on the classification of the Coleoptera of the division Languriidæ. The author pointed out the characters which, in his opinion, were available for the systematic arrangement of this family of Coleoptera, and for its division into genera. The subject had hitherto not received the attention it deserved, and several errors had gained currency, owing to the hasty and insufficient way in which the structure of these insects had been analysed. He added an analytical table of about forty genera, many of those proposed being new. Further notice of the American genera would soon appear in Messrs. Godman and Salvin's "Biologia Centrali-Americana."

Mathematical Society, April 7.—Sir J. Cockle, F.R.S., President, in the chair.—The following papers were read, or taken as read:—On the intersections of a circle and a plane curve, by Prof. Genese.—A new theory of harmonic polygons, by the Rev. T. C. Simmons.—On some properties of simplicissima, with especial regard to the related spherical loci, by Mr. W. J. C. Sharp.—On Briot and Bouquet's theory of the differential equation $F\left(u, \frac{du}{dx}\right) = 0$, by Prof. Cayley, F.R.S.—Two points in the plane of a triangle and a cubic through them, by R. Tucker.—A tetrahedral note, by Dr. Wolstenholme.

EDINBURGH

Royal Society, April 4.—Dr. J. Murray, Vice-President, in the chair.—Prof. Tait communicated a note by Prof. Cayley, on a formula for $\Delta^n 0^i/n^i$, when n and i are very large numbers.—Mr. R. Kidston read the first part of a paper on the fossil flora of the Radstock series of the Somerset and Bristol coal-fields (Upper Coal-measures).—Dr. Sang read a paper on the achromatism of the four-lens eye-piece, describing a new arrangement of the lenses. He also read a note on an effective arrangement for observing the passage of the sun's image across the wires of a telescope.—Prof. Turner read a communication by Mr. F. E. Beddard, on the structural characteristics of certain new or little-known earthworms. Five new species found in Australia and New Zealand were treated of.—Prof. J. Geikie discussed the geology and petrology of St. Abb's Head.

PARIS

Academy of Sciences, April 12.—M. Janssen, President, in the chair.—On the relations that exist between cyclones and concurrent storms and hurricanes, by M. H. Faye. From [illegible] attentive study of the synoptical storm charts of the United States Signal Service, the author is able to confirm the conclusions already drawn by M. Marié-Davy from the meteorological observations made at the Paris Observatory so far back as the year 1864. It is shown (1) that tornadoes, hurricanes, and hailstorms are simply secondary phenomena directly associated with the central cyclonic movement; (2) that in the United States their trajectories have no general relation either to the isobars or to the normal atmospheric currents; (3) that these relatively short trajectories are parallel to the vast cyclonic trajectories at the moment when these local phenomena arise; (4) that they all lie on the right flank of the cyclone itself, which may thus be regarded as a complex meteorological system accompanied on its right side by whole colonies of destructive tornadoes and hurricanes with their attendant waterspouts, hailstorms, and torrential downpours, all moving together across seas and continents. The whole movement is regulated by the simple law of the mechanics of fluids, which determines the formation of spirals or vortices in the upper atmospheric regions. The surprising variety of the physical effects produced by the movement is simply due to the descending vortex, which, as in our electric machines, suffices to bring into contact and set in violent motion aërial masses lying far apart, with their consequent differences of temperature, and aqueous particles either frozen or in a state of vapour and of positive or negative tension.—On the term "latex" in botany, by M. A. Trécul. In reply to some recent objections made to his comprehensive use of this term, the author here justifies its application both to the contents of the laticiferous vessels and to the product of the secreting ducts. The numerous facts brought together in this communication tend clearly to establish the fundamental resemblance between the physical and physiological properties of the contents of the laticiferous vessels properly so called, and of the secreting tubes, so that these two classes of vessels are properly grouped together under the common designation of vessels of the latex.—On some essays made at sea with Capt. Fleuriais' new collimating gyroscope, by M. de Jonquières. The results are given of the observations made with this instrument by Lieut. Baule, of the steamer *La Gascogne*, during a recent trip from Bordeaux to Brazil. Although this was the first application of the apparatus, the observer was able by its means to record the rolling of the vessel with considerable accuracy.—On earthquakes, by M. Oppermann. The author substantially accepts the general view of seismologists, that these disturbances are mainly due to the pressure exercised on the upper crust by the aqueous vapour formed at great depths below the surface by filtration through fissures or porous rocks.—On the winter egg of Phylloxera, by M. P. de Lafitte. The author replies to some misleading statements recently made by M. Donnadieu, and calculated to affect the issue of the experiments which are now being carried on throughout the wine-growing districts of France.—On a complementary experiment relative to waterspouts, by M. Ch. Weyher. The experiments hitherto described had reference only to the artificial formation of the "*buisson*," that is, of the two inverted cones superimposed at their summits. Here a further process is described, by means of which the author has succeeded in producing the complete waterspout, with its tube of vapour attached on the one hand to the centre of the *buisson* and on the other to the centre of the revolving drum placed 3 metres above the surface of the water. To effect this all that is needed is to project a jet of vapour to the neighbourhood of the axis of the vortex, or, better still, simply to heat the water in the large reservoir sufficiently to cause some vapour to rise.—A study of the alkaline vanadates (continued), by M. A. Ditte. Here are treated the vanadates of soda: VO_5,NaO; $2VO_5,NaO$; $3VO_5,2NaO$; $3VO_5,NaO$; $VO_5,2NaO$; $VO_5,3NaO$; and VO_5,NaO.—On the upheaval of the south-west coasts of Finland, by M. Venukoff. The topographic surveys recently carried out in Finland show once more that the shores of the Baltic are continually rising. Since the surveys of 1810–15 several islands have become peninsulas, while many shallows have become islands or beaches. On the south-west coast and in the neighbouring Aland Archipelago many places are pointed out by the inhabitants which a few years ago were under water, but which are now grazing-grounds, market-gardens, or cornfields. The local authorities are now taking steps, by means of which the progress of this geological phenomenon may in future be determined with absolute certainty and accuracy.—The sudden death was announced of M. Thollon in the midst of his labours connected with the construction of a great solar chart, on which the distinction between the telluric and solar rays would have been indicated. M. Thollon's name will always be remembered in connexion with spectroscopic studies, which have been greatly advanced by his improved spectroscope and by the device suggested by him for distinguishing rays of solar origin from those due to the terrestrial atmosphere.

---

[1] This phenomenon is difficult to explain, but it suggests the possibility of a transverse as well as a longitudinal contraction in muscular fibre.—March 29, 1887.

BERLIN

Physical Society, April 1.—Prof. von Helmholtz in the chair.—Dr. Pernet spoke on the comparison of barometers, and drew attention to a number of sources of error which must be avoided when reading off a barometer. The speaker has carried out a series of comparisons with corrected standard barometers, aneroid barometers, and the standard barometers of different stations. He finds that the standard barometers of Berlin and Paris correspond exactly within the limits of errors of observation; aneroids do not yield anything like the same exactness that may be obtained with syphon-barometers.—Dr. Pernet also brought a new form of standard mercurial thermometer before the Society, and explained its construction. It consists essentially of the usual bulb and fine tube, which is widened out above and below into two receptacles each of which is capable of holding a mass of mercury corresponding to a column representing 50°. By means of this arrangement the instrument is easily graduated, and admits of any desired adjustment of the zero and graduation; also by varying the amount of mercury with which it is filled the same exactness in reading which is possible between 0° and 50° can be obtained even up to 200°.—Dr. Kotter spoke on the mean rate of flow of a fluid from a small aperture. This rate, as is well known, depends not only upon pressure, weight, &c., but upon a certain constant which is called the coefficient of efflux, and which has been determined to be 0·62. The speaker gave an account, in their historical order, of a number of researches which have been made with a view to determining this coefficient mathematically, and then proceeded to explain his own methods of calculation, which lead to the value $\frac{\pi}{2+\pi}$ established by Kirchhoff and Rayleigh.—Dr. Konig exhibited a direct-vision spectroscope constructed by Wernicke, which is contained in a glass tube instead of a wooden one, and thus admits of the internal arrangement of the instrument being seen.

PRACTICAL ELECTRICITY

Practical Electricity. By W. E. Ayrton, F.R.S. (London: Cassell and Co., 1887.)

PROF. AYRTON'S book on Practical Electricity fills a gap, and is well fitted for the purpose for which its author has designed it. The book comprises the substance of the first year's course for students of electrical technology in the City and Guilds Central Institution at South Kensington, with some additional matter, which is chiefly in small type. The subject of Current is treated first, then comes Electromotive Force or Potential Difference, and afterwards Resistance. This is undoubtedly the logical order, though, as Prof. Ayrton points out, this sequence appears complicated to the minds of learners, from the fact that in the definitions of the Paris Congress the volt is made to depend on the ohm and the ampere. The practical units, ampere, ohm, volt, &c., are used throughout, but a little more space might have been given with advantage to the definitions of these units. Take, for instance, the definition of an ampere, § 6. After showing by means of a most instructive and well-arranged experiment (Fig. 1) that a current produces magnetic, chemical, and thermal effects, and further, that the chemical changes are the same in two or more voltameters of the same kind, Prof. Ayrton proceeds:—"We shall therefore *define the strength of a current as being directly proportional to the amount of chemical decomposition produced in a given time; and the current that deposits* 0·00111815 *gramme or* 0·017253 *grain of silver per second on one of the plates of a silver voltameter, the liquid employed being a solution of silver nitrate containing from* 15 *to* 30 *per cent. of the salt*, we shall call an *ampere*,' and take it as our unit current." But frequently a beginner will at once wish to know why these special numbers, which will seem to him unnecessarily complex, should have been taken. Why not select ·001 gramme of silver rather than ·00111815? will be an obvious question, to which no answer is given. Surely, too, four significant figures would be sufficient. Besides, this is not the definition of ampere adopted by the Paris Congress, and it involves the experiments of someone on the electro-chemical deposition of silver. The experiments given in the early part of Chapter II. do not need the previous definition of the *unit current*, and from them the fact that a current exerts on a magnet a definite force depending on its strength and (§ 22) on the dimensions and position of its circuit is established. Thence the idea of the current which exerts on a definite magnet a unit force is easily reached, and from this we get the ampere of the Congress definition, which is found, by careful experiment, to deposit so many grammes of silver per second.

So, too, the definition of the "volt" would have been clearer if the excellent illustration of difference of potential given in § 40, Fig. 28, had been carried a little further, and it had been pointed out that, just as the water loses potential energy in falling from one level to another, and that loss is measured by the quantity of water multiplied by the difference in pressure, so the electric current loses energy in passing from one point to another, and that loss is measured by the quantity of electricity multiplied by the difference of electrical potential. But these, perhaps, are points which can be better brought out by a teacher in explaining difficulties to his class.

The book is, we believe, the first in England which accepts distinctly the resolutions of the Paris Congress as a basis. Another novelty to be found in it is the use of the letters P.D. (potential difference) for the old abbreviation E.M.F. This is a change for which, if it can be satisfactorily introduced and accepted, all teachers will be thankful, for it will get rid of the confusion existing between the resultant electrical force at a point, and the electromotive force between two points, which is not a force at all.

The plan of the book has been already indicated. Starting from the definition of an ampere, the various means of measuring currents are described, and full details are given of the methods for carrying out the experiments, for recording results graphically and otherwise, and for drawing conclusions from the experiments. The illustrations show clearly the arrangement of apparatus in each case. In Prof. Ayrton's laboratory the apparatus required for any one series of observations is mounted permanently on the same board; the student finds everything ready, and the necessary connexions made when he begins. As to the desirability of this, there will no doubt be some difference of opinion; but with large classes of beginners some such plan is necessary. Thus, Fig. 15 shows the apparatus for investigating the action of a current on a magnet. The large coil C C is so arranged that the current can be made to traverse it eight, twelve, or sixteen times, and its effect on the magnet *g g* observed; or the coil C C can be replaced by *c c* of half the radius, which has four turns on it; or, again, C C can be used simultaneously with *c c*, the current being

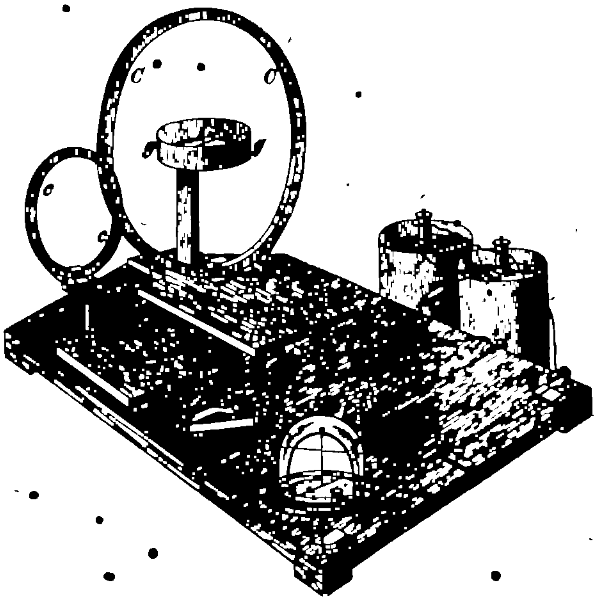

FIG. 15.[1]

---

[1] We are indebted to Messrs. Cassell for the blocks used to illustrate this article.

sent in opposite directions through the two. *w w* is a resistance by means of which the current may be varied at will, and G a galvanometer.

Chapter III introduces us to difference of potential, and here the writer describes in a practical form the experiments for the verification of some of the ordinary laws of statical electricity.

Ohm's law and its proof follow in Chapter IV, and it is shown that the resistance of a conductor remains unchanged so long as its other physical conditions are the same. § 80 gives the definition of the "legal ohm." It is not quite accurate to speak of its having been legalised, at any rate in this country; though, as the letter from the B.A. Committee on Electrical Standards, which is printed at the end of the preface, shows, the question of its adoption as a legal standard is now before the Government. Various methods of comparing resistances follow, with full practical details, but the important one due to Prof. G. C Foster, for comparing two nearly equal resistances, has been omitted from § 97.

Batteries and other forms of current-generators are next considered, with details as to their construction and use; and an account of the methods of determining thei E.M.F. and resistance is given.

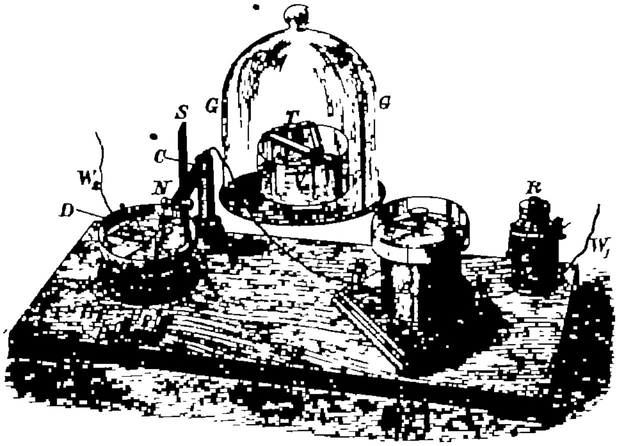

FIG. 157.

"Insulation" is the title of Chapter VI., and many o the practical hints given under this head are of grea value.

In the next chapter, condensers, and the methods of constructing them and of measuring their capacities, are treated of. We find also a chapter devoted to commercial ammeters and voltmeters, which gives in an easily accessible form particulars as to some of the best known of these instruments, with practical methods of testing and calibrating. In Fig. 157 we have the arrangement of apparatus for comparing an ammeter with a silver voltameter. R is an adjustable resistance of a useful character, made of a number of washers of carbonised cloth which can be pressed into close contact by a screw. Latimer Clark's cell is described in § 214, in the H form. A simpler pattern consists of a test-tube with a platinum wire sealed through the bottom. The end of this is covered with pure mercury, and above this is a layer of mercurous sulphate, with a saturated solution of sulphate of zinc above all. A rod of clean zinc dips into the zinc sulphate passing through the cork which closes the test-tube, and the whole is kept tight with marine glue.

In an appendix Kirchhoff's laws of divided circuits are considered. The method of treating such problems introduced by Maxwell, and which has recently been illustrated at some length by Prof. Fleming, is also referred to.

Another point of importance which calls for notice is the number of examples introduced by way of illustration; some of these are completely worked out, others left as exercises for the student.

The book concludes with some specimens of the instructions for experiments which are given to students at the City and Guilds Institution, with the apparatus with which each experiment is performed. Of these instructions there are four; and many who use the book will wish their number was larger. We will close this notice by quoting the last of them

To calibrate an ammeter by means of a silver voltameter (the apparatus required has been figured above): —

"PRELIMINARY.—The voltameter consists of a platinum dish containing a 25 per cent. solution of silver nitrate, and in which a silver plate is immersed. An adjustable carbon resistance is provided, by means of which the current passing through the voltameter can be maintained constant during each experiment, and can be varied in the different experiments.

"EXPERIMENTS.—(1) Carefully clean, dry, and weigh the platinum dish, the *approximate* weight of which is 78 grammes

"(2) Pour the solution of silver nitrate into the dish, and place it on the three brass pins provided for its reception, and which are electrically connected with the left-hand binding-screw on the board Immerse the silver plate in the solution, and clamp it in such a position that its edges are equally distant from the sides and bottom of the dish.

"(3) Turn the small milled head at the top of the ammeter so that the pointer of the ammeter comes opposite the zero on the scale, if not there already. Place the copper connecting-wire in the mercury cups marked A and C (which cuts out the voltameter), and adjust the carbon resistance until a convenient current flows round the ammeter. Remove the connecting-wire.

"(4) Quickly insert the connecting-wire in the mercury cups marked A and B, carefully noting the instant at which the circuit was completed. Allow the current to pass for a convenient time (ten to thirty minutes, according to the strength of the current used), and keep the current constant by the adjustable resistance. Note the temperature of the room during the experiment, and, at the end of the interval decided on, quickly break the circuit.

"(5) Empty the solution from the dish into its bottle, and carefully wash the deposited silver with distilled water. Then fill the dish with distilled water, and allow it to stand ten to fifteen minutes Again wash with water, alcohol, and ether, dry over the spirit-lamp, and cool in the desiccator.

"(6) Carefully determine the increase of weight due to the silver deposited on the dish.

"(7) Calculate the strength of current used in the experiment, assuming that one ampere deposits 1·11815 milligrammes of silver per second.

"(8) Repeat the experiment with several different strengths of current.

"(9) Tabulate your results in some convenient form, and write them with your name on the card, on which you will find recorded the results of previous experiments."

SPOLIA ATLANTICA

Spolia Atlantica. (1) Contributions to the Knowledge of the Salpidæ, by M. P. A. Traustedt; (2) Remarks on some of the Oceanic Annulata, by G. M. R. Levinsen; (3) Contributions towards the Morphology and Systematic Arrangement of the Pteropoda, by J. E. V. Boas. (Copenhagen, 1885-86.)

THE three monographs which at the instance, and under the supervision, of the Directors of the Zoological Museum of Copenhagen, have been included in one quarto volume under the title of "Spolia Atlantica," originally appeared in the Transactions of the Danish Royal Society of Natural Sciences. But although bound together, each monograph in this *édition de luxe* is complete in itself, with separate title-page, table of contents, descriptive plates, and all other necessary means of separate reference, while the convenience of readers not acquainted with Danish has been amply considered by the addition of Latin and French translations of the descriptions of the animals, and of many other important parts of the text.

The first of this triplet of monographs, which deals with the so-called "aggregate" and "solitary" forms of the several species of Salpæ, is based on a study of the exceptionally complete collections preserved in the Zoological Museum of Copenhagen, for which that institution is mainly indebted to Prof. Steenstrup, at whose suggestion and under whose direction Herr Traustedt compiled his memoir. The monograph presents a clear and comprehensive description of all the well-established species of Salpæ with their distinctive dual forms, and unqualified praise may be given to the care with which the figures have been drawn, and the admirable manner in which, by means of pale blue outlines, the delicacy and transparency of the bodies of the animals have been represented.

In treating of the Salpidæ, it is impossible to forget how much of our knowledge of these curious animals is due to the observations of Chamisso, the clever author of "Peter Schlemihl," who, while serving as naturalist in the exploring expedition of the Russian commander Kotzebue, first discovered that the "aggregate" or chain Salpa and the "solitary" Salpa were not distinct species, as had been supposed, but only parts of the perfect organism of one species. By the discovery of this fact, which Chamisso ingeniously, but, as subsequent investigations have shown, too fancifully, explained on the hypothesis that these animals were subject to a law of "alternation of generations," new and highly important paths of morphological inquiry were opened. Yet, singularly enough, nearly thirty years passed after the publication, in 1819, of Chamisso's treatise "De Animalibus quibusdam e Classe Vermium Linneana (de Salpis)" before his observations were tested by further scientific investigation. About the middle of the century Meyen and Vogt turned their attention to the curious and interesting phenomena connected with the embryonic development of the Salpæ. These inquiries were soon followed by the still more important researches of Profs. Krohn and Huxley, the latter of whom in a paper entitled "Observations upon the Anatomy and Physiology of Salpa and Pyrosoma," which appeared in the Phil. Trans. 1851, has shown that Chamisso erred in his explanation of the nature of a "chain Salpa," which, to use Mr. Huxley's words, "is nothing more homologically than a highly individualised generative organ."

Herr Traustedt does not enter into the question of the embryonic development of the Salpidæ, and hence his work gives no information regarding the physiology of these animals, nor does he in any way refer to the various hypotheses that have been advanced in explanation of the character of the "aggregate" and "solitary" forms. For such information the student must go elsewhere. As a guide to the anatomical structure of both forms in the eleven species described and drawn by the author, the memoir will, however, be found of great service, while it contains much useful information as to the geographical distribution of these animals not to be found elsewhere.

In the treatise on "Some Oceanic Annulata" Herr Levinsen supplies many interesting details regarding various members of the families Alciopidæ and Typhloscolecidæ, together with descriptions of several species of Sagitta, to which are added lists of their geographical distribution. In this, as in the memoir on the Pteropoda, the illustrations are worthy of all praise.

The memoir by Dr. Boas, which constitutes the last and longest of the series, treats at great length of the morphology, systematic arrangement, and geographical distribution of the Pteropoda. The materials employed by the author were derived in part from the extensive collections in the Zoological Museum of Copenhagen made by, or under the direction of, Prof. Steenstrup, and in part from numerous specimens placed at the writer's disposition by Profs. Dohrn, Möbius, Leche, and Spengel. It is worthy of note that a very large proportion of the specimens referred to as belonging to the Museum of Copenhagen were obtained from amateur collectors; Danish naval officers, captains of merchant ships, and travellers having responded with alacrity to Prof. Steenstrup's appeal for help in obtaining samples of these and other animals from remote regions.

OUR BOOK SHELF

Complete Hand-book on the Management of Accumulators. By Sir David Salomons, Bart. Second Edition, revised and enlarged. (London: Whittaker and Co., 1887.)

THE author has for some years past had an installation at his country residence for the purpose of lighting it and for working motors which drive the machinery in his large and well-equipped workshop. He has used accumulators, as he informs us, ever since they may be said to have been produced in commercial form in 1882. No expense nor trouble have been spared in making this installation a model one, and experiments have been made on many points in connexion with the subject. As the whole installation has been made and worked under his immediate personal superintendence, he has acquired a considerable amount of experience, the result of which, as far as it regards the management of accumulators, he places before the public in this work.

After a general description of cells of the E.P.S. and Elwell-Parker type, he proceeds to give directions for setting up and charging them. The causes of, and remedies for, "buckling" and "scaling" are discussed. The harm caused by too rapid a discharge is pointed out, and methods for preventing it are explained, as well as various devices for regulating the E.M.F. of the charging current and that on the line. The method of cleaning and "re-pasting" the plates is explained, and various hints are given for the management of the battery. In an appendix is a description of the arrangement of his accumulator house, a photograph of the interior of which forms the frontispiece to his book. He also gives a brief account of the history of the installation, from which we learn that the total cost of buildings and installation has been about 6000*l*., that the number of lamps is about 500 of 20-candle power, but that the greatest number used at any one time has rarely exceeded 200, and that an arc lamp taking 40 or 50 amperes and one or two motors have been used together with them. The expenses—including wages, coal, oil, waste, washers, repairs, lamp renewals, &c.—were, in 1886, 210*l*., or at the rate of ¼*d*. per 20-candle lamp per hour. He does not, however, say anything as to the cost of the accumulators; and as to the length of time which they may be expected to last he only says vaguely that "the cells may last for years in perfect order if all the instructions here given are properly attended to." His present accumulators were only put up in August 1885, those previously erected having proved to be unsatisfactory.

It is a pity that the useful information in this work is not conveyed in better language. In what is intended as a workshop hand-book we do not look for the elegance of an Addison; but we do want plain English. As an example of the language we may quote the following sentence from the preface: "Only cells of the Electrical Power Storage Company, of Messrs. Elwell-Parker, and their type, are dealt with, because at this moment there is probably no other better kind, or largely in use." The meaning of this is clear, though even that is more than may be said of other sentences in the book.

Among minor faults we protest against the coinage of such a hideous word as "acidometer," by which, apparently, is meant the instrument commonly known as a hydrometer; we do not think "s.g." is an improvement on the ordinarily accepted abbreviation for specific gravity; and we object to the plural "dynamos" as against the ordinary rule of our language which gives us "potatoes" and "echoes."

A more serious error is found in the "Index of Terms" on the back of the title-page—

"Watt = volt × ampere = measure of force or energy."

We should recommend the author to get the work revised by some onewho understands the rudiments of science as well as those of the English language.

School Hygiene: The Laws of Health in Relation to School Life. By Arthur Newsholme, M.D. (London: Swan Sonnenschein, Lowrey, & Co., 1887.)

About the importance of the matters dealt with in this little book there can, of course, be no dispute; and, as Dr. Newsholme points out in his preface, they have engaged the serious attention of many School Boards and Committees, and been made the subject of a good deal of useful legislation. Most school-managers still have something to learn about the principles of school hygiene, and many of them will, no doubt, find in Dr. Newsholme's volume exactly the kind of information they want. He discusses the subject under two heads, "Schools" and "Scholars." Under the first head he presents his ideas on questions connected with the choice of sites for schools, the construction of school buildings, school furniture, lighting of school-rooms, general principles of ventilation, natural ventilation, ventilation and warming, and draining arrangements. In the part relating to "Scholars" he has chapters on mental exercise, excessive mental exercise, age and sex in relation to school work, muscular exercise and recreation, rest and sleep, children's diet, children's dress, baths and bathing, eyesight in relation to school life, communicable diseases in schools, and school accidents. Dr. Newsholme has studied his subject thoroughly, and his conclusions are all the more valuable because they have been to a large extent suggested by his experience as a medical officer of health, and as a medical referee for various schools and training colleges.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to insure the appearance even of communications containing interesting and novel facts.*]

Mass, Weight, and Dynamical Units

If the laws of dynamics were made solely for the use of engineers, as a celebrated engineer declared of rivers that they were intended to feed canals, it might be conceded to Prof. Greenhill that it would not be *necessary* that the more abstract notion of mass should be distinguished from that of weight, and that the fundamental equation of dynamics might conveniently be taken as $P = W\frac{f}{g}$, where W is the weight (or mass) of the body moved expressed in pounds or tons, &c., and P the force producing in it the acceleration f, and reckoned in the same units. But a pound weight as a force is a variable unit, unless it is taken at some particular place (as Greenwich), and then the corresponding value of g must be employed (though the variation of g on the surface of the earth is not so great as often to need to be taken account of by the engineer); and so the astronomer and physicist, as well as the student of abstract dynamics, are right in demanding a less arbitrary measure of force than one founded on the force acting vertically downwards on a body at the earth's surface, as well as an absolute constant belonging to each body (its *mass*) independent of time and place. I conceive, therefore, in spite of Prof. Greenhill's arguments, that, in the interest of clearness of thought, as well as to avoid the practical inconvenience of a variable unit of force, the notions of mass and weight must be kept distinct, and the equation $W = Mg$, as a special case of the general equation $P = Mf$, still insisted on by all teachers of dynamics, at any rate to non-engineering students; while it would be well for engineers also (*me judice*) to have their dynamics cast in the same mould as the rest of the scientific world.

I should not have troubled you with the above very obvious remarks had I not wished to observe, *à propos* of Mr. Geoghegan's suggestion of names for units of velocity and acceleration in NATURE of April 7 (p. 534), that it is highly desirable that a convenient and consistent *notation*, as well as *nomenclature*, should be adopted for the several dynamical units.

With respect to the particular suggestion that *vel* and *cel* (or *velo* and *cele*, as used by Mr. Lock in his forthcoming book, "Dynamics for Beginners") should be employed for the units of speed and acceleration in the foot-second system, I regard it as an almost fatal objection that the accepted C.G.S. system having appropriated the words *dyne* and *erg* for its units of force and work has a prior right to *vel* and *cel* for its units of speed and acceleration; namely, the centimetre per second, and the centimetre per second per second. If so, the units of the foot-second system might be called the *footvel* and the *footcel*.

Names for the dynamical units are, however, I think, of less importance than a convenient and suggestive notation for them. I have endeavoured to devise such a notation (or, rather, to fill up and complete notations which have more or less come into use) in a table, which is now under the consideration of a Committee of the Association for the Improvement of Geometrical Teaching, and which is substantially as follows.

In a perfectly general system, let L, M, T stand respectively for the fundamental units of length, mass, and time, and let V, A, U, Δ, E stand for the units thence derived of speed, quickening (acceleration), momentum or impulse, force, and energy or work respectively: then the statement that the unit of speed is the speed of the unit of length *per* unit of time is naturally expressed thus, $V = L/T$. On the same principle we should have—

$$A = V/T = L/TT,\ U = MV = ML/T,\ \Delta = MA = ML/TT,\ E = L\Delta = LML/TT.$$

This may be simplified, using the analogy of the fluxional notation, by writing $\dot{L}$ for L/T and $\ddot{L}$ for L/TT. Then $\dot{L}$, $\ddot{L}$ may take the place of V and A, and we have—

$$U = M\dot{L},\ \Delta = M\ddot{L},\ E = L\Delta = LM\ddot{L}.$$

Names for the several units are hardly needed in the general system.

In the C.G.S. system the units of length, mass, and time are respectively the centimetre, gramme, and second, denoted by O, G, S. Then if U_G, Δ_G, E_G denote the units of momentum or impulse, force, and energy or work, we have, on the same principle as before, $\dot{O}$, $\ddot{O}$ to denote the speed of a centimetre per second and the acceleration of a centimetre per second per second respectively, and the equations—

$$U_G = G\dot{O},\ \Delta_G = G\ddot{O},\ E_G = O\Delta_G = OG\ddot{O}.$$

If *names* for all these units are required, we may use these: *vel, cel, mom, dyne, erg*; and we may say, a *mom* is a *gramme-vel*, a *dyne* is a *gramme-cel*, and an *erg* a *centimetre-dyne*.

In the F.P.S., or British system, the units of length, mass, and time are respectively the foot, pound, and second, denoted by F, P, S. Then, if U_P, Δ_P, E_P denote the units of momentum or impulse, force, and energy respectively, we have, on the same principles, $\dot{F}$, $\ddot{F}$ to denote the speed of a foot per second and the acceleration of a foot per second per second respectively, and the equations—

$$U_P = P\dot{F},\ \Delta_P = P\ddot{F},\ E_P = F\Delta_P = FP\ddot{F}.$$

I propose as names for these units: *footvel, footcel, poundem, poundal, pounderg*. I should have called the unit of force a *pound-dyne* or *poundyn*, but that *poundal* has already obtained general acceptance.

The foregoing are all absolute units. The corresponding (Greenwich) gravitation-units are the *pound-weight* = 32·19 *poundals*, the *foot-pound* = 32·19 *poundergs*, and the *second-pound* (as it has been proposed by Prof. Unwin to name the gravitation-unit of momentum, or time-integral of a pound-weight through one second) = 32·19 *poundems*; so that to convert absolute F.P.S. units into gravitation-units, or *vice versâ*, it is only necessary to divide or multiply by 32·19, since the acceleration due to gravity at Greenwich = 32·19 $\ddot{F}$.

It is, I think, comparatively unimportant whether the *names* above suggested are, all of them, accepted or not; but the *notation* will, I believe, be found a great aid to the beginner in fixing in his mind the dimensions of the different magnitudes, and an effective safeguard against the too common confusion of units of force, impulse, and work. I doubt whether in speaking much would be gained by saying "*footvel*" instead of "foot per second," or "*footcel*" instead of "foot per second per second," while in *writing*, the symbols $\dot{F}$ and $\ddot{F}$ might be always used and read either way.

Harrow, April 12

Units of Weight, Mass, and Force

FAR be it from me to interfere between Mr. Alfred Lodge and Prof. Greenhill; but, whilst leaving Mr. Lodge to his fate and Prof. Greenhill, perhaps, as an engineer, I may be permitted to offer a few remarks on the general question. First, then, it appears to me that Prof. Tait's thoroughgoing condemnation of certain phrases of the engineering vernacular, and of the grave errors of certain writers, has been strained in some quarters to mean a general charge against engineers of inability to think or write clearly on the physical laws which lie at the root of their every-day practice. Such an unqualified charge is on the face of it absurd; for otherwise we must confess that the lives' work of Thomson and Tait has been a total failure as regards its influence on the truly practical men of their generation. Can this be so?

Prof. Greenhill's remarks on the abominable semi-numerical equation $W = Mg$, or $\frac{W}{g} = M$, I most heartily welcome [where W is a mass and g a numeric; the moment writers on dynamics, who use the gravitation system, pass from merely proportional equations to their physical interpretation, then must we face with them this most wretched equation]. But perhaps it will be at once a surprise and a gratification to Prof. Greenhill to know that a whole (academic) generation of Scottish University engineering students has been taught to eschew this same equation as an unclean thing, and to adopt the mode of thought clearly set forth in the last two paragraphs of his letter of February 28. Some five or six years ago I was myself so taught by one who is now, alas! no more. The possibility of thus clearing of cant not only the engineering but the purely mathematical mind seems to me, as indeed Prof. Greenhill indicates, to be a direct consequence of the acceptance by Thomson and Tait of the British Imperial pound as the unit of mass or quantity of matter.

Having fixed, then, for good and all, the unit of mass, and taking the British foot and the second as the units of time and length respectively, the unit of force defines itself in virtue of Newton's Second Law. To this unit—the British unit of force—Prof. James Thomson has given, as nearly everyone knows, the name "poundal." Now the most convenient practical unit of force, for physicists as well as engineers, is not the poundal, but the gravitation at the earth's surface of the unit of mass, a quantity which is not absolutely constant, the inconvenience so arising being, however, practically unimportant, or at most involving a reduction to an arbitrary standard. To pass, then, from a force expressed in poundals to a force expressed in units of gravitation of the Imperial pound at the standard place, one simply wants to know how many poundals go to the gravitation of the Imperial pound at that place—in other words, the change ratio. The answer is simple: the numeric g for the standard place; for a force equal to the gravitation of the Imperial pound at the standard place acting upon a mass of one Imperial pound would generate a momentum per second of g (numeric) pounds mass × feet per sec. per sec.; and the poundal a momentum per second of one pound mass × feet per sec. per sec.; and by Newton's Second Law the ratio of the forces is, therefore, the numeric g. What more does the physicist or engineer want to know? How many poundals go to the gravitation of a ton mass at the standard place? Answer, the numeric 2240 g. Could anything be simpler? The difficulty is to find the difficulty, or to assign the *raison d'être* of the so-called gravitation unit of mass.

When the old unnatural gravitation unit of mass is abandoned, and the transition from the natural unit to the gravitation unit of force made by means of the change ratio, the vicious use of the word mass to denote the result of dividing by the numeric g the mass of a body in standard pounds (viciously on the same system called the weight and denoted by W) ceases; and the dire confusion between weight and mass becomes a thing of the past. The emancipation of the term weight from its bondage to mass would appear to have afforded opportunity for its use wherever it might be of service in suggesting or denoting gravitation. For example, there are three units, each called a pound, viz. the Imperial British unit of mass, the gravitation of the same mass at any the same place on the earth's surface, and the pound sterling. Physicists, like Sir Wm. Thomson and Prof. Tait, use terms such as "pound weight," "gramme weight"; similarly we have "pound mass" coming into use; and probably we shall soon hear of "pound money." Prof. Greenhill, with his strong engineering sympathies, objects to the time-honoured "pounds per square inch" being rendered "pounds weight per square inch"; and if I may presume to offer an opinion, the old phrase is already cumbrous enough. Still, if Prof. Tait and Prof. Greenhill ultimately agree that there is anything to be gained in perspicuity, for the sake of the weaker members perhaps it might be well for us to put in practice, on some occasions, the injunction to sacrifice all rather than cause our brother to offend.

Some one might possibly step in to draw attention to the fact that the pages of even our own great high priest of exact applied science are disfigured by $\frac{W}{g}$; but sure I am that were Rankine now with us he would lead the way with Prof. Greenhill in a crusade against the apologists for the obscurity of which W/g is the symbol. Take, for example, Rankine's bold introduction of the dynamical unit of quantity of heat. Take the opinion of

Clausius, than whom none could be a more unprejudiced witness. "At the same time in the theoretical development of the mechanical theory of heat, in which the relation between heat and work often occurs, the method of expressing heat in mechanical units effects such important simplifications that the author has felt himself bound to drop his former objections to the method on the occasion of the present more connected exposition of that theory." ARCHD C. ELLIOTT

Edinburgh, April 18

Seismometers

I HAVE long ago learnt not to look for any fair recognition of my work in seismometry on the part of Prof. John Milne, and when he accuses me of appropriating without acknowledgment the work of others it is time to decline further controversy with him. The points raised in his last communication (NATURE, April 14, p. 559) are sufficiently answered in mine of December 11 (p. 172). I there quoted part of a letter written by Prof. Chaplin, now of Harvard University, then of Tokio, and Secretary of the Seismological Society of Japan, under whose eyes the events occurred to which Prof. Milne refers. I did not quote the whole of Prof. Chaplin's letter, because it contained sentences I was unwilling to give except under the strongest provocation. After referring to my seismograph in the words already quoted (p. 172), Prof. Chaplin continues:—

"I do not remember that in the discussions on your machine Mr. Gray ever claimed to have invented a similar machine, and I am surprised to know that he makes that claim now: On this and other points it appears to me that Messrs. Gray and Milne have not treated your inventions and investigations with fairness, and that you have just grounds for complaint. I am willing you should make such use of this note as you see fit."

As to the question of priority, this judgment, from a man at once unprejudiced, most competent to form an opinion, and fully informed of the matter in dispute, must (so far as I am concerned) close a discussion of which your readers cannot but be weary. With your permission I shall give, in a later number of NATURE, an example of the excellent work which Prof. Sekiya is now doing with my instruments in Japan

J. A. EWING

University College, Dundee, April 16

April Meteors

THE Lyrids have, this year, offered a somewhat scanty display, though a few brilliant meteors have been seen shooting from the usual radiant-point.

In 1884 April 19, this shower was very rich, the horary number of its meteors for one observer being about 22, but in the following year, 1885, it exhibited a considerable decline, the hourly rate being only 3. In 1886 I obtained no observations, owing to the bright moonlight and in the present year, on April 20, the horary number was slightly more than 2, so that the numerical character of the recent display has fallen far short of some of its apparitions in preceding year

On the night of April 17, this year, the shower had not visibly opened, for none of its meteors were recorded in a 2½ hours' watch. On each of the nights of the 18th and 19th the sky was closely observed for 4½ hours, but the Lyrid shower was very feeble, and only furnished 1 meteor per hour On the 20th, in 3 hours I noted 7 Lyrids, and these were brilliant.

The average radiant-point from the three nights was at 269° + 32°, and there is confirmation that this point advances in R.A with the time, though not to the marked degree ascribed in NATURE for May 7, 1885, p 5 But the meteors from this stream have been so scarce at their late recurrence that it has been very difficult to ascertain the exact radiant for each night. Moreover, these Lyrids move with great apparent velocity, flashing out with extreme suddenness and they are gone, together with the faint streaks sometimes accompanying them, before the eye is enabled to catch the directions with satisfactory precision

On the four nights April 17 to 20 inclusive, I noticed 70 shooting-stars belonging to the minor systems of the Lyrid meteoric epoch, and amongst these the best was that of a radiant of very swift, short meteors at 231° + 17°, a few degrees west of β Serpentis. This stream is not new, for I saw a well-defined shower of Serpentids from the same point during my observations of the Lyrids in 1885, on April 19–20 (NATURE, May 7, 1885, p 6).

In this and in previous years I have also recorded some meteors ascending in very long flights from a radiant centre close to θ Libræ, at 235° − 15°. This is the only observation of this shower at the April period, though Lieut.-Colonel Tupman found a pair of radiants near the position assigned in the first week of March 1869–70.

I subjoin a short list of bright meteors seen here while watching the progress of the Lyrids, and I should be glad to hear that any of these had been observed elsewhere.

Date	Hour	Mag	Apparent Path		Notes	Radiant
			From	To		
1887	h m		° °	° °		
April 19	13 13	♀	269 + 11	269 + 1	Swift, streak	Lyrid
19	13 46	♃	303 + 61½	56 + 65½	Swift, streak	279° + 13°
20	9 48	1	211 + 7	194 − 4	Very swift	Lyrid
20	10 29½	>2	243 + 14	234 + 5	Swift, streak	Lyrid
20	10 47	1	239 + 53	269 + 62½	Slow, train	206° + 18°
20	12 28	>1	303 + 40	316 + 40½	Very swift	Lyrid

Bristol, April 22 W. F. DENNING

Vertical Decrement of Temperature and Pressure

IN NATURE of March 10 (p. 437), Mr. Maxwell Hall gives an interesting table of the vertical distribution of temperature and pressure in Jamaica, and, apparently in happy ignorance of the dangers of the process known as extrapolation, goes on to apply the results of observations extending to a maximum height of only 7400 feet to the determination of the probable temperature of meteorites in extra-terrestrial space. As he expresses a desire to know whether any similar results have been found in India, and as I have on several occasions during the past ten years discussed the vertical distribution of temperature and pressure in this country, I gladly take this opportunity of referring him to my papers on the meteorology of the North-West Himalaya, and on the temperature of North-Western India, published in the "Indian Meteorological Memoirs," vols i. and ii. From the latter I extract the following table on the mean decrement of temperature up to a height of 12,000 feet, computed from the observations of twenty-five stations combined in various ways. For each month an interpolation formula of the form

$$T = T_0 + ah + bh^2 + ch^3,$$

was computed, and by its means the decrements from sea-level to 1000 feet, 1000 to 2000 feet, &c., were calculated. Finally, the average decrement for the twelve months was computed, and is here given in an abridged form The curves for the several months differ very widely from one another, those for the summer giving the most rapid decrement at sea-level, and the decrement increasing with altitude in winter:—

Height	Mean temperature decrement
Feet	° F.
0 to 2000	6·16
2000 to 4000	5·87
4000 to 6000	5·61
6000 to 8000	5·37
8000 to 10000	5·16
10000 to 12000	4·98

The mean height of the barometer at sea-level in the region in question, the centre of which lies a little north of Simla, is about 29·8 inches; the mean at 6000 feet is 24·1 inches, and the mean at 12,000 feet about 19·4 inches. With these data, and adopting Mr. Hall's formula

$$\delta T = \lambda . \delta P + \mu (\delta P)^2,$$

we find $\lambda = 2^\circ{\cdot}979$ and $\mu = 0^\circ{\cdot}02$. These coefficients do not differ widely from Mr. Hall's values, which are $2^\circ{\cdot}92$ and $0^\circ{\cdot}08$ respectively. At the limit of the atmosphere, where $\delta P = 29''{\cdot}8$, δT would be $-106^\circ{\cdot}5$, which would give, as the mean temperature of external space, about −30° F., the mean temperature at sea-level being 77° F

Taking the simplest formula, $\delta T = \lambda\, \delta P$, we find $\lambda = 3^\circ{\cdot}19$, which is almost identical with the value quoted by Mr. Hall from an early volume of NATURE, but which, if it held good to the limit of the atmosphere, would make the temperature of external space about −18° F., since the mean temperature at sea-level is 77° F.

The only conclusion to be drawn from such observations is that the vertical decrement of temperature on mountains varies greatly with locality as well as season, and the results obtained for one locality cannot be fully applied to another, much less extended to determine the temperature at the superior limit of the atmosphere.

An interesting point of resemblance between Mr. Hall's observations and those made on the Himalaya is that the diurnal range of temperature diminishes to a minimum at about 5000 feet, and then increases with increasing elevation.

Allahabad, March 30 S. A. HILL

Royal Society's *Soirée*

MAY I be permitted, through the columns of NATURE, to ask, on behalf of the Sub-Committee appointed to make arrangements for the forthcoming *soirée* of the Royal Society, that Fellows and others who have apparatus or objects of scientific interest suitable for exhibition on that occasion will communicate at once with the Secretaries or myself. HERBERT RIX,

Royal Society, Burlington House Asst. Sec. R.S.

HOMERIC ASTRONOMY[1]

II.

TURNING to the second great constellation mentioned in both Homeric epics, we again meet traces of remote and unconscious tradition. Yet less remote, probably, than that concerned with the Bear. Certainly less inscrutable. For recent inquiries into the lore and language of ancient Babylon have thrown much light on the relationships of the Orion fable.

There seems no reason to question the validity of Mr. Robert Brown's interpretation of the word by the Accadian *Ur-ana*, "light of heaven" ("Myth of Kirke," p. 146). But a proper name is significant only where it originates. Moreover, it is considered certain that the same brilliant star-group known to Homer no less than to us as Orion, was termed by Chaldeo-Assyrian peoples "Tammuz" (Lenormant, *Origines de l'Histoire*, t. i. p. 247), a synonym of Adonis. Nor is it difficult to divine how the association came to be established. For about 2000 B.C., when the Euphratean constellations assumed their definitive forms, the belt of Orion began to be visible before dawn in the month of June, called "Tammuz," because the death of Adonis was then celebrated. It is even conceivable that the heliacal rising of the asterism may originally have given the signal for that celebration. We can at any rate scarcely doubt that it received the name of "Tammuz" because its annual emergence from the solar beams coincided with the period of mystical mourning for the vernal sun.

Orion, too, has solar connexions. In the Fifth "Odyssey" (121-24), Calypso relates to Hermes how the love for him of Aurora excited the jealousy of the gods, extinguished only when he fell a victim to it, slain by the shafts of Artemis in Ortygia. Obviously, a sun-and-dawn myth slightly modified from the common type. The post-Homeric stories, too, of his relations with Œnopion of Chios, and of his death by the bite of a scorpion (emblematical of darkness, like the boar's tusk in the Adonis legend), confirm his position as a luminous hero (R. Brown, *Archæologia*, vol. xlvii. p. 352; "Great Dionysiak Myth," chap. x. § v). Altogether, the evidence is strongly in favour of considering Orion as a variant of Adonis, imported into Greece from the East at an early date, and there associated with the identical group of stars which commemorated to the Accads of old the fate of Dumuzi (*i.e.* Tammuz), the "Only Son of Heaven."

It is remarkable that Homer knows nothing of stellar mythology. He nowhere attempts to account for the names of the stars. He has no stories at his fingers' ends of translations to the sky as a ready means of exit from terrestrial difficulties. The Orion of his acquaintance—the beloved of the Dawn, the mighty hunter, surpassing in beauty of person even the divinely-born Aloidæ—died and descended to Hades like other mortals, and was there seen by Ulysses, a gigantic shadow "driving the wild beasts together over the mead of asphodel, the very beasts which he himself had slain on the lonely hills, with a strong mace all of bronze in his hand, that is ever unbroken ("Odyssey," xi. 572-75). His stellar connexion is treated as a fact apart. The poet does not appear to feel any need of bringing it into harmony with the Odyssean vision.

The brightest star in the heavens is termed by Homer the "dog of Orion." The name *Seirios* (significant of sparkling), makes its *début* in the verses of Hesiod. To the singer of the "Iliad" the dog-star is a sign of fear, its rising giving presage to "wretched mortals" of the intolerable, feverish blaze of late summer (*opora*). The deadly gleam of its rays hence served the more appropriately to exemplify the lustre of havoc-dealing weapons. Diomed, Hector, Achilles, "all furnish'd, all in arms," are compared in turn, by way of prelude to an "*aristeia*," or culminating epoch of distinction in battle, to the same brilliant but baleful object. Glimmering fitfully across clouds, it not inaptly typifies the evanescent light of the Trojan hero's fortunes, no less than the flashing of his armour, as he moves restlessly to and fro ("Iliad," xi. 62-6). Of Achilles it is said:—

"Him the old man Priam first beheld, as he sped across the plain, blazing as the star that cometh forth at harvest-time, and plain seen his rays shine forth amid the host of stars in the darkness of night, the star whose name men call Orion's Dog. Brightest of all is he, yet for an evil sign is he set, and bringeth much fever upon hapless men. Even so on Achilles' breast the bronze gleamed as he ran" (xxii. 25-32).

In the corresponding passage relating to Diomed (v. 4-7), the *naïve* literalness with which the "baths of Ocean" are thought of is conveyed by the hint that the star shone at rising with increased brilliancy through having newly washed in them.

Abnormal celestial appearances are scarcely noticed in the Homeric poems There are neither eclipses[1] of sun or moon, nor comets, nor star-showers. The rain of blood, by which Zeus presaged and celebrated the death of Sarpedon ("Iliad," xvi. 459, also xi. 54) might be thought to embody a reminiscence of a crimson aurora, frequently, in early times, chronicled under that form; but the portent indicated is more probably an actual shower of rain tinged red by a microscopic alga. An unmistakable meteor, however, furnishes one of the glowing similes of the "Iliad" By its help the irresistible swiftness and unexpectedness of Athene's descent from Olympus to the Scamandrian plain are illustrated.

"Even as the son of Kronos the crooked counsellor sendeth a star, a portent for mariners or a wide host of men, bright shining, and therefrom are scattered sparks in multitude; even in such guise sped Pallas Athene to earth, and leapt into their midst" ("Iliad," iv. 75-9).

In the Homeric verses the Milky Way—the "path of souls" of prairie-roving Indians, the mediæval "way of pilgrimage"[2]—finds no place. Yet its conspicuousness, as seen across our misty air, gives an imperfect idea of the lustre with which it spans the translucent vault which drew the wondering gaze of the Ionian bard.

The point of most significance about Homer's scanty astronomical notions is that they were of home growth. They are precisely such as would arise among a people in an incipient stage of civilisation, simple, direct, and childlike in their mode of regarding natural phenomena, yet incapable of founding upon them any close or connected reasoning. Of Oriental mysticism there is not a vestige. No occult influences rain from the sky. Not so much as a square inch of foundation is laid for the astrological superstructure. It is true that Sirius is a "baleful star"; but it is in the sense of being a harbinger of hot weather. Possibly, or probably, it is regarded as a concomitant cause, no less than as a sign of the August droughts; indeed the *post hoc* and the *propter hoc* were, in those ages, not easily separable; the effect, however, in any case, was purely physical, and so unfit to become the starting-point of a superstition.

---

[1] Continued from p. 588.

[1] Gorlitz finds a prediction of a solar eclipse at "Odyssey," xx 357, but the expression appears quite indefinite and figurative

[2] To Compostella. The popular German name for the Milky Way is still *Jakobsstrasse*, while the three stars of Orion's belt are designated, in the same connexion, *Jakobsstab*, staff of St James.

The Homeric names of the stars, too, betray common reminiscences rather than foreign intercourse. They are all either native, or naturalised on Greek soil. The transplanted fable of Orion has taken root and flourished there. The cosmopolitan Bear is known by her familiar Greek name. Boötes is a Greek husbandman, variously identified with Arkas, son of Callisto, or with Ikaros, the luckless mandatory of Dionysos. The Pleiades and the Hyades are intelligibly designated in Greek. The former word is usually derived from *plein*, to sail; the heliacal rising of the "tangled" stars in the middle of May having served, from the time of Hesiod, to mark the opening of the season safe for navigation, and their cosmical setting, at the end of October, its close. But this etymology was most likely an after-thought. Long before rules for navigating the Ægean came to be formulated, the "sailing-stars" must have been designated by name amongst the Achaian tribes. Besides, Homer is ignorant of any such association. Now in Arabic the Pleiades are called *Eth Thuraiyâ*, from *tharwa*, copious, abundant. The meaning conveyed is that of many gathered into a small space; and it is quite similar to that of the Biblical *kîmah*, a near connexion of the Assyrian *kimtu*, family (R. Brown, "Phainomena of Aratus," p. 9; Delitzsch, "The Hebrew Language," p. 69). Analogy, then, almost irresistibly points to the interpretation of Pleiades by the Greek *pleiones*, many, or *pleos*, full; giving to the term, in either case, the obvious signification of a "cluster."

Of the Hyades, similarly, the "rainy" association seems somewhat far-fetched. They rise and set respectively about four days later than the Pleiades; so that, as prognostics of the seasons, it would be difficult to draw a permanent distinction between the two groups; yet one was traditionally held to bring fair, the other foul weather. There can be little doubt that an etymological confusion lay at the bottom of this inconsistency. "To rain," in Greek is *huein*; but *hus* (cognate with "sow") means a "pig." Moreover, in old Latin, the Hyades were called *Suculæ* ("little pigs"); although the misapprehension which he supposed to be betrayed by the term was rebuked by Cicero (*De Nat. Deorum*, lib. ii. cap. 43). Possibly the misapprehension was the other way. It is quite likely that "Suculæ" preserved the original meaning of "Hyades," and that the pluvious derivation was invented at a later time, when the conception of the seven stars in the head of the Bull as a "litter of pigs" had come to appear incongruous and inelegant. It has, nevertheless, just that character of *naïveté* which stamps it as authentic. Witness the popular names of the sister-group—the widely-diffused "hen and chickens," Sancho Panza's "las siete cabrillas," met and discoursed with during his famous aërial voyage on the back of Clavileño, the Sicilian "seven dovelets,"—all designating the Pleiades. Still more to the purpose is the Anglo-Saxon "boar-throng," which, by a haphazard identification, has been translated as Orion, but which Grimm, on better grounds, suggests may really apply to the Hyades (*Teutonic Mythology*, trans. by J. S. Stallybrass, vol. ii. p. 729). It is scarcely credible that any other constellation can be indicated by a term so manifestly reproducing the "Suculæ" of Latin and Sabine husbandmen.

The Homeric scheme of the heavens, then, (such as it is), was produced at home. No stellar lore had as yet been imported from abroad. An original community of ideas is just traceable in the names of some of the stars; that is all. The epoch of instruction by more learned neighbours was still to come. The Signs of the Zodiac were certainly unknown to Homer, yet their shining array had been marshalled from the banks of the Euphrates at least 2000 years before the commencement of the Christian era. Their introduction into Greece is attributed to Cleostratus of Tenedos, near, or shortly after, the end of the sixth century B.C. By that time, too, acquaintance had been made with the "Phœnician" constellation of the Lesser Bear, and with the wanderings of the planets. Astronomical communications, in fact, began to pour into Hellas from Egypt, Babylonia, and Phœnicia about the seventh century B.C. Now, if there were any reasonable doubt that "blind Melesigenes" lived at a period anterior to this, it would be removed by the consideration of what he lets fall about the heavenly bodies. For, though he might have ignored formal astronomy, he could not have remained unconscious of such striking and popular facts as the identity of Hesperus and Phosphorus, the Sidonian pilots' direction of their course by the "Cynosure," or the mapping-out of the sun's path among the stars by a series of luminous figures of beasts and men.

Thus the hypothesis of a late origin for the "Iliad" and "Odyssey" is negatived by the astronomical ignorance betrayed in them. It has, however, gradations; whence some hints as to the relative age of the two epics may be derived. The differences between them in this respect are, it is true, small, and they both stand approximately on the same astronomical level with the poems of Hesiod. Yet an attentive study of what they have to tell us about the stars affords some grounds for placing the "Iliad" the "Odyssey," and the "Works and Days" in a descending series as to time.

In the first place, the division of the month into three periods of ten days each is unknown in the "Iliad," is barely hinted at in the "Odyssey," but is brought into detailed notice in the Hesiodic calendar. Further, the "turning-points of the sun" are unmentioned in the "Iliad," but serve in the "Odyssey," by their position on the horizon, to indicate direction; while the winter solstice figures as a well-marked epoch in the "Works and Days." Hesiod, moreover, designates the dog-star (not expressly mentioned in the "Odyssey") by a name of which the author of the "Iliad" was certainly ignorant. Besides which an additional constellation (Boötes) to those named in the "Iliad" appears in the "Odyssey" and the "Works and Days"; while the title "Hyperion," applied substantively to the sun in the "Odyssey," is used only adjectivally in the "Iliad." Finally, stellar mythology begins with Hesiod; Homer (whether the Ionian or the Ithacan) takes the names of the stars as he finds them, without seeking to connect them with any sublunary occurrences.

To be sure, differences of place and purpose might account for some of these discrepancies, yet their cumulative effect in fixing relative epochs is considerable; and, even apart from chronology, it is something to look towards the skies with the "most high poet," and to retrace, with the aid of our own better knowledge, the simple meanings their glorious aspect held for him.

A. M. CLERKE

ON ICE AND BRINES[1]

I.

THE composition of the ice produced in saline solutions, and more particularly in sea-water, has frequently been the object of investigation and of dispute. It might be thought that to a question of whether ice so formed does or does not contain salt, experiment would at once give a decisive answer. Yet, relying on experiment alone, competent authorities have given contradictory answers. All agree that ice, whether formed artificially in the laboratory by freezing sea-water, or found in nature as one of the various species of sea-water ice, retains, in one form or another, and with great tenacity, the salt existing in solution in the water. The question at issue is whether this salt is to be attributed to the solid matter of the ice or to the liquor mechanically adhering to it, from which it is impossible to free it. Most bodies, and especially those which take a crystalline form, are easily purified and freed from all suspected foreign matter, with a view to analysis, by the simple operation of washing and drying. It is impossible to wash the crystals, formed by freezing a saline solution, with distilled water, because they melt at a temperature below that at which distilled water freezes. The effect of the addition of a small quantity of distilled water to a quantity of saline ice is at first the anomalous one, that what was a wet sludge is transformed into a dry crystalline powder. It is of course impossible to dry the ice by heat, and to do so by more intense freezing would be begging the question. The experimental difficulties therefore account for some of the divergence of opinion on the subject. The mixed character of the substances examined has also much to do with it. As a rule it may be said that those investigators who have confined their observations to the laboratory have concluded that the ice forming when saline solutions of moderate concentration, including sea-water, are frozen, is pure ice, and the salt from which it is impossible to free it entirely belongs to the mother-liquor, while those who have collected and examined sea-water ice in high latitudes have come to the opposite conclusion.

---

[1] Paper read before the Royal Society of Edinburgh, by J. Y. Buchanan on March 27 last.

During the Antarctic cruise of the *Challenger* I made a number of observations on the sea-water ice found in those regions, and relying principally on the fact that the melting temperature of the ice was markedly lower than that of fresh-water ice, and that it was impossible by any of the ordinary means familiar to chemists for freeing crystals from adhering mother-liquor to materially reduce its salinity, I came to the conclusion that the ice forming in freezing sea-water is not a mixture of pure ice and brine, but that it contains the salt found in it in the solid state either as a crystalline hydrate or as the anhydrous salt, but most probably as a hydrate. In dealing with this subject, Dr. Otto Pettersson ("Water and Ice," p. 302) quotes my observations, and also rejects the view that "sea-ice is in itself wholly destitute of salts, and only mechanically incloses a certain quantity of unfrozen and concentrated sea-water." He founds his belief on the fact that numerous analyses of specimens of sea-water ice have shown that the constitution of the saline contents of different specimens of ice differs for each specimen, and is always different from that of the saline contents of sea-water. Were the salinity due to inclosed unfrozen and concentrated sea-water, we "ought to find by chemical analysis exactly the same proportion between Cl, MgO, CaO, SO_3, &c., in the ice and in the brine as in the sea-water itself." He adduces numerous examples of analyses of specimens of sea-water ice from the Baltic and from the Arctic Seas to show that this is not the case. Calling the percentage of chlorine in each case 100, he found in various sea-waters the percentage of SO_3 vary from 11·49 to 11·89. In specimens of sea-water ice it varied from 12·8 to 76·6, and in brines separating from the ice and remaining liquid at – 30° C. it varied from 1·14 to 1·16.

This argument appears conclusive. In order to explain all the phenomena observed in connexion with sea-water ice he cites Guthrie's investigations, which went to show that in freezing saline solutions, under a certain concentration, pure ice is formed at a temperature which falls from 0° C., when the amount of salt dissolved is infinitely small, to a certain definite temperature when the solution contains a certain definite percentage of salt. Further abstraction of heat then produces solidification of the solution as a whole, in the form of a crystalline hydrate, of constant freezing and melting-point. To such hydrates, Guthrie gave the name of cryohydrates. Pettersson quotes the following as being particularly applicable to the case of sea-water:—

The cryohydrate of		Contains per cent. of water		Solidifies at ° C.
NaCl	..	76·39	...	– 22
KCl	..	80·00	...	– 11·4
$CaCl_2$	...	72·00	.	– 37·0
$MgSO_4$	...	78·14	..	– 5·0
Na_2SO_4	.	95·45	...	– 0·7

And he refers more particularly to the cryohydrate of Na_2SO_4 forming and melting at – 0°·7.

Now the bearing of Guthrie's experiments is to show that, while at sufficiently low temperatures, and with suitable concentration, the water will solidify along with one or other of the salts in solution, until this low temperature and high concentration are attained, pure ice must be the result of freezing.

The abnormal phenomena attending the formation and the melting of ice in saline solutions and sea-water, find a natural explanation in an observation which I have frequently quoted, and which Dr. Pettersson mentions in a footnote at p. 318, namely, that "a thermometer immersed in a mixture of snow and sea-water which is constantly stirred indicates – 1°·8 C." If this is true, it is clear that my melting-point observations proved nothing. On repeating the experiment I found it confirmed, and took the opportunity this winter of investigating the matter more closely. The paper read before the Royal Society of Edinburgh contains the first portion of the results. It deals with the subject under two heads, namely, (*a*) the temperature at which sea-water and some other saline solutions freeze, and the chemical constitution of the solid and the liquid into which they are split by freezing; and (*b*) the temperature at which pure ice melts in sea-water and in a number of saline solutions of different strengths.

(*a*) The freezing experiments were limited to sea-water and solutions of NaCl comparable with sea-water.

Chloride of Sodium.—Four solutions were used, and they were intended to contain 3, 2·5, 2, and 1·5 per cent. NaCl respectively. Forty grammes of this solution, in a suitable beaker, were immersed in a freezing mixture of such composition as to give a temperature from 2° to 2°·5 C. below the freezing temperature expected. The temperature at which ice began to form (if necessary after adding a minute splinter of ice) was noted, and the freezing was allowed to continue with constant stirring till the temperature had fallen 0°·2 C. A specimen of the mother-liquor was removed, and the chlorine in it determined; the chlorine in the original solution had been determined before. The beaker was then removed from the freezing bath and allowed to melt. The temperature in all cases rose during melting exactly as it had fallen during freezing. In the following table are given the means of the temperature at which ice began to form in the original solution, and that of the liquid when the sample of brine was taken, and the means of the chlorine found in the original solution and in the brine sample

Mean Freezing Temp.	– 1°·875 C.	– 1°·63	– 1°·30	– 0°·975
Mean per cent. Cl.	1·87	1·60	1·30	0·98

It will be seen that, in the dilute solutions experimented with, the percentage of chlorine expresses, in terms of the Centigrade scale, the lowering of the freezing-point of the solution.

Sea-Water.—Similar experiments were made with sea-water of different degrees of concentration. In sea-water from the Firth of Clyde containing 1·84 per cent. of chloride, ice forms at − 1°·9 C. The following results are from means of closely-agreeing results:—

Freezing temperature	− 2°·0	− 1°·5	− 1°·0	− 0°·5
Per cent. chlorine	1·94	1·445	0·963	0·475
Difference	0·06	0·055	0·037	0·025

Sea-water resembles a chloride of sodium solution, containing the same percentage of chlorine, and the resemblance is closer the greater the dilution. When the beaker was removed from the freezing-bath, the temperature rose during melting as it had fallen during freezing. In these experiments, which had for their object the determination of the temperature at which the crystals melted, as well as that at which they began to form in the water, it was impossible to remove a sample for analysis large enough to enable the sulphuric acid to be determined in it.

For this purpose a series of observations were made, using quantities of 300 grammes of sea-water. Freezing was continued usually until the temperature had fallen 0°·3 C. below that at which crystals began to form. The mother-liquor was then separated from the crystals by means of a large pipette with fine orifice, before removing the beaker from the freezing bath. The magma of crystals was then brought rapidly on a filter and drained by means of the jet pump. The ice, thus drained, was then melted, and the three fractions were analysed. In the following table (I) the results of four experiments are given. In the one column (W) will be found the weight of the original water taken and of the fractions into which it was split in freezing; in the other (R) will be found the ratio of SO_3 to Cl found by analysis, the chlorine being set down as 100; thus, in I, the percentage of chlorine found in the crystals, melting at the lowest temperature, was 1·497, and that of the SO_3, 0·174, the ratio (R) is therefore 11·62.

TABLE I.—*Freezing sea-water—Analyses of fractions.*

No. of Experiment.	I.		II		III		IV.	
Nature of Water...	Forth 100 %.		Mother-liquor		Clyde 100 %.		Clyde 50 %.	
	W.	R	W.	R	W.	R	W.	R.
Original water	300	11·83	90	11·67	300	11·5[illegible]	300	11·21
Mother-liquor	170·6	11·67	—	11·83	100	11·57	78	11·67
Drainings			—	—	9[illegible]	11·56	109	—
Crystals	106	11·62	[illegible]3	11·[illegible]	[illegible]	11·[illegible]7	106	11·44
,, ...	[illegible]·5	11·11	—	—	—	—	—	—

It will be seen that the ratios (R) found for mother-liquor, drainings, and ice agree with one another quite as closely as those found in samples of pure sea-water from different localities. It is to be remembered that in these experiments the water was frozen *gently*, that is, the rate of abstraction of heat was low, the temperature of the freezing bath being regulated so as to be about 2° C. below the freezing temperature of the solution. Much of the error and uncertainty about the freezing of saline solutions arises from the violence of the methods employed. Judging then by the constancy of the relation of the percentage of Cl to SO_3 we see that in sea-water, frozen at moderate temperatures, the composition of the saline contents of the original water, the mother-liquor and the ice is identical; and we are justified in concluding that it is probable that the saltness of the ice is due to unfrozen and concentrated sea-water adhering to it. Ice forming in even very weak saline solutions closely resembles snow (which is ice forming in air), and has the same remarkable power of retaining mechanically several times its weight of water or brine.

A strict account was kept of the heat removed from the sea-water while the freezing was going on. In Table II. will be found the number of heat-units (gramme ° C.) removed during the freezing in the case of Nos. III. and IV.; and this number, divided by 79·25, gives the weight of pure ice, which could have been formed at 0° C. by the removal of heat.

TABLE II.—*Calculation of ice formed.*

			III.	IV.
Weight of original water (grammes)		W	300	300
Per cent. Cl in ditto		c	1·836	0·923
Per cent. Cl in mother-liquor		K	2·212	1·153
Weight of mother-liquor	$W\frac{c}{K}=$	L	249·0	239·3
Weight of ice	W − L =	I	51·0	60·7
Mean freezing temperature (° C)...........		—	− 2·05	− 1·05
Heat abstracted (grammes ° C)		—	4230	5193
Equivalent ice formed (grammes)		—	53·4	65·5

Sea-water, like other saline solutions, is easily cooled several degrees below its freezing-point before crystals begin to form. While cooling down to and below what was known to be its freezing-point, simultaneous observations of the temperature of the sea-water and the freezing bath were made from half-minute to half-minute. From these observations, the rate of abstraction of heat for different differences of temperature of sea-water and bath was found. At a given moment a minute splinter of ice (weighing much less than a drop of water) was introduced. Crystals immediately began to form, and the temperature rose in from ten to fifteen seconds to the freezing-point. During the freezing the temperatures of bath and sea-water were observed at regular intervals. The heat removed is thus made up of that eliminated during the few seconds when freezing began and the temperature rose to the freezing-point, which is found by multiplying the rise of temperature by the weight of liquid, and that removed during the subsequent cooling, which is deduced from the duration of the operation and the rate of loss of heat observed before freezing commenced. The specific heat of the solution is taken as unity. In the table are further given the weight of the sea-water used, the percentage of chlorine in the original water and in the mother-liquor, the weight of the mother-liquor on the assumption that it contains all the salt of the original water, and, by difference, the weight of the ice formed. The agreement between the two quantities of ice formed as calculated by the different methods is as close as could be expected.

It has thus been shown that the composition of the saline contents of the ice formed as above described is the same as that of the original water, and this of itself is almost conclusive that the salt is contained in adhering brine and not as a solid constituent of the ice. Assuming that this is so the amount of ice formed as deduced from the composition of the mother-liquor agrees well with the amount deduced from the thermal exchange taking place during the freezing.

It has, moreover, been proved by Guthrie, Rüdorff, and others, that, in solutions of the salts occurring in sea-water, ice does separate out at first, and continues to separate out until the concentration has become many times greater than that of sea-water. Assuming that in sea-water all the chlorine is united to sodium, 87 per cent. of the water would have to be removed as ice before a cryohydrate would form, and if it contained nothing but sulphate of soda in the proportion corresponding to the sulphuric acid formed in it, over 90 per cent. of the water would have to go as ice, before the cryohydrate would be formed.

In my experiments, about 15 per cent. of the weight of the water was frozen out as ice, causing a lowering of freezing-point by 0°·3 C. In nature it is probable that the ice forming at the actual freezing surface does so at an almost uniform temperature, the local concentration produced by the formation of a crystal of ice being immediately eliminated by the mass of water below. In the interstices of the crystals there will be retained a weight of slightly concentrated sea-water at least as great as that of the ice crystals. These retain the brine in a meshwork of cells, and, as the thickness of the ice covering increases, and the freezing surface becomes more remote, the ice and the brine become more and more exposed to the atmospheric rigours of the Arctic winter. The brine will continue to deposit ice until its concentration is such that, for example, the cryohydrate of NaCl is ready to separate out. It probably will separate out until it comes in conflict with, for instance, the chloride of calcium or the chloride of magnesium, which will retain some of the water, without solidifying, even at the lowest temperatures. At the winter quarters of the *Vega* brine was observed oozing out of sea-water ice and liquid at a temperature of – 30° C. It was very rich in calcium and especially magnesium chlorides. In fact, *it is probably quite impossible by any cold occurring in nature to solidify sea-water.*

The residual and unfreezable brine which remains in considerable quantity liquid when sea-water is frozen, must also remain in greater or less quantity when fresh water is frozen. All natural waters, including rain-water, contain some foreign and usually saline ingredients. If we take chloride of sodium as the type of such ingredients, and suppose a water to contain a quantity of this salt equivalent to one part by weight of chlorine in a million parts of water, then we should have a solution containing 0·0001 per cent. of chlorine, and it would begin to freeze and to deposit pure ice at a temperature of –0°·0001 C.; and it would continue to do so until, say, 999,000 parts of water had been deposited as ice. There would then remain 1000 parts of residual water, which would retain the salt, and would contain, therefore, 0·1 per cent. of chlorine, and would not freeze until the temperature had fallen to –0°·1 C. This water would then deposit ice at temperatures becoming progressively lower, until, when 900 more parts of ice had been deposited, we should have 100 parts residual water, or brine as it might now be called, containing 1 per cent. of chlorine, and remaining liquid at temperatures above – 1°·0 C. When 90 more parts of ice had been deposited, we should have 10 parts of concentrated brine containing 10 per cent. of chlorine and remaining liquid at – 10° C. In the case imagined, we assume the saline contents to consist of NaCl only, and with further concentration the cryohydrate would no doubt separate out and the mass become really solid. On reversing the operations, that is, warming the ice just formed, we should, when the temperature had risen to – 10° C., have 999,990 parts ice and 10 brine containing 10 per cent. chlorine. Now, owing to the remarkable fact (which is dealt with at length in the second part of the paper) that pure ice, in contact with a saline solution, melts at a temperature which depends on the nature and the amount of the salt in the solution, and is identical with the temperature at which ice separates from a solution of the same composition on cooling, the brine liquefies more and more ice at progressively rising temperatures, until, as before, when the temperature of the mass has risen to –0°·1 C., it consists of 999,000 parts of ice and 1000 parts of liquid water, containing 1 part of chlorine. The remainder of the ice will melt at a temperature gradually rising from –0°·1 C. to 0° C.

The consideration of this example furnishes an easy explanation of the anomalous behaviour of ice, formed from anything but the very purest distilled water, in the neighbourhood of its melting-point. This subject has been studied with great care and thoroughness by Pettersson. The apparent expansion of all but the very purest ice, when cooled below 0° C., is ascribed by him in part to solid saline contents of the ice which exercise a disturbing and unexplained influence on its physical properties. Viewed in the light of the fact that the presence of even the smallest quantity of saline matter in solution prevents the formation of ice at 0° C. and promotes its liquefaction at temperatures below 0° C., we see that this apparent expansion of the ice on cooling is probably due to the fact that we are dealing not with homogeneous solid ice but with a mixture of ice and saline solution. As the temperature falls this solution deposits more and more ice and its volume increases. But the increase of volume is due to the formation of ice out of water and not to the expansion of a crystalline solid already formed.

In Table III. are given the volumes occupied by the ice (with inclosed brine) formed by freezing 100,000 c.c. (at 0° C.) of a water containing chloride of sodium equivalent to 7 grammes chlorine in 1,000,000 cubic centimetres (at 0° C.).

TABLE III.—*Water containing 7 parts Cl in 1,000,000.*

Temp. ° C.	Water frozen. c.c.	Ice formed c.c.	Brine remaining. c.c.	Ice and Brine c.c.	Pettersson III. Vol. of ice at T c.c.	Diff
T	V_1	v_1	V_2	v_2	P	$P - v_2$
– 0·07	99000	107979	1000	108979	108980	1
– 0·10	99300	108306	700	109006	109007	1
– 0·15	99533	108561	467	109028	109038	10
– 0·20	99650	108687	350	109037	109048	11
– 0·40	99825	108879	175	109054	109057	3

The volume of the ice formed on freezing this water is compared with that observed by Pettersson in freezing a sample of the distilled water in ordinary use in the laboratory.

It will be seen that the volumes observed by Pettersson agree very closely with those calculated for a water containing 7 parts of chlorine in a million.

The irregularities in the melting-points of bodies like acetic acid, to which Pettersson refers, are without doubt due to a perfectly similar cause.

Also the very low latent heat observed by Pettersson for sea-water is to be explained by the fact that the salt retains a considerable proportion of the water in the liquid state even at temperatures many degrees below the freezing-point of distilled water.

The *plasticity* of ice and the motion of glaciers receive a simple and natural explanation when we see, as in Table III., that, if the water from which this ice is produced contains no more than 7 parts of chlorine per million, it will, in the process of thawing, when the temperature has risen to –0°·07 C., consist to the extent of 1 per cent. of its mass of liquid brine or water. The water considered in Table III. is certainly not less free from foreign ingredients than rain or snow. It follows, therefore, that a glacier, in a climate where the temperature is for the greater part of the year above 0° C., must have a tendency to *flow*, owing to the power of saline solutions to deposit ice and to dissolve it at temperatures below 0° C.

(*To be continued.*)

NOTES

The Endowed Schools Committee, of which Sir Lyon Playfair is Chairman, after sitting for a year and a half, have agreed to their Report. This is not yet issued, but it is known that the Committee have reported in favour of endowed schools being in future largely used for the promotion of scientific and technical education. The Report also recommends that local authorities should be authorised to employ local rates for founding or contributing to laboratories and workshops in such schools in order to promote practical scientific education.

Last week an important Conference was held at Oxford for the consideration of questions connected with the University Extension Scheme. The meetings were attended by many members of the University, local delegates, and others interested in this method of University development. There can be no doubt whatever as to the good work done by University Extension lecturers. Unfortunately, however, it is hard to obtain the funds which are necessary for the complete success of the experiment. One speaker urged that "the University should lead the way by the creation of a Jubilee Fund, and so stimulate local efforts." To this Prof. Rogers replied that the University was "positively poor." Prof. Rogers added that the result of an appeal to London Companies "had not been favourable," but that the Charity Commissioners might perhaps be willing to do something for the movement.

THE American Exhibition to be opened in the Earl's Court neighbourhood on May 9 will contain much that ought to be of scientific interest. The large encampment of American Indians will be found to contain a great variety of types, and ought to prove attractive to ethnologists. The machinery department will contain many illustrations of the successful applications of science, especially in the section directed to machines for the production and application of electricity. Under mining and metallurgy there will be a large collection of minerals, ores, and stones, besides specimens of metallurgical products. In the department of education and science will be found illustrations of the varied educational appliances and apparatus used in the United States, exhibits from the many institutions and organisations which exist in the States, and a very varied collection of scientific and philosophical instruments.

A NEW scientific journal—*Centralblatt für Physiologie*—has made its appearance this month in Germany. It is edited by Dr. S. Exner, of Vienna, and Dr. J. Gad, of Berlin, who have the advantage of the co-operation of the Berlin Physiological Society. The journal will be issued once a fortnight.

A MONUMENT to Galileo has been erected in Rome, on the Via Pincio, fronting the old Medici Palace, now occupied by the French Embassy, where he was kept a prisoner, in 1637, during his prosecution by the Inquisition. The monument consists of a column with a pedestal, on which is the following inscription in the Italian language:—"Erected in memory of Galileo Galilei, who was kept a prisoner in this Palace, for having seen that the earth moves round the sun."

DR. R. MÜLLER publishes, in the April number of *Mittheilungen aus dem Gebiete des Seewesens*, the results of an investigation as to whether or not the popular idea of equinoctial gales, the existence of which was contested some time ago as regards this country by Mr. Scott (NATURE, vol. xxx. p. 353), holds good for the Adriatic Sea. For this purpose the hourly records of the anemometer at Pola, from 1876–86, were used. During this period strong winds or gales were registered on 607 days, 63 per cent. of which occurred in the winter season (October to March). The months with least wind were naturally June and July; then a tolerably regular increase in the number of days with stormy winds took place till the end of January. A considerable decrease occurred in February, while March had the greatest number of stormy days. The result arrived at is that, for the Adriatic, no important influence can be attributed to the equinoctial seasons, especially during the autumnal equinox. Dr. Müller also quotes a similar investigation made by the *Deutsche Seewarte*, for the years 1878–83, for the German coasts, with nearly similar results; the percentage of storms for the winter season being 80 per cent., and for the summer season only 20 per cent. The greatest number of storms occurred in November and December, March having 14 per cent., and September 3 per cent. only.

AT a recent meeting of the Italian Meteorological Society, reported in its *Bollettino mensuale* for February last, the Committee enumerated the meteorological stations lately established by it abroad, viz. one in Tripoli, two in the Argentine Republic, three in Uruguay, one in Colombia (South America), and one in Mexico, and notified their intention of shortly establishing others on the Patagonian coasts of the Pacific, and in some of the islands near Cape Horn. Among other matters discussed was the proposed suppression of the *Bollettino decadico*—which has reached its fourteenth yearly volume, and which contains the observations made at ordinary stations, and at stations in the Alps and Apennines, for decades—as the increasing work of the Society renders its publication difficult. The monthly means of these observations appear in the *Bollettino mensuale*, but the last published are for March 1886.

ON the night of April 12, at about 11.30, a brilliant meteor was seen in Verdalen, in Norway. It appeared in the east, and went in a southerly direction. At first the colour was a pure white, but during the progress of the meteor it changed into green and yellow. The lustre of the body was very bright, and its greatest apparent size was about that of an ordinary plate. On the meteor disappearing from view behind a mountain ridge, a sudden brilliancy seemed to indicate that it had burst into fragments, but no detonation was heard. It left a faint trail of smoke behind, about a few yards in length, which remained for a few seconds in the sky, then disappeared.

ON April 13 a shock of earthquake was felt at Lisbon, and in Malta and Sicily. Considerable alarm was caused in Jersey at a few minutes past 3 o'clock on the morning of April 21 by a slight shock of earthquake, the direction of which was from south-west to north-west. There was so loud a noise that at first some persons fancied guns were being fired. About the same time a smart shock of earthquake was experienced in Guernsey. A decided tremor of the earth, lasting about three seconds, and accompanied by a rumbling noise, was felt in all parts of the island.

THE death is announced of Dr. Nathaniel Lieberkuhn, Professor of Anatomy at the University of Marburg, on April 14, at the age of sixty-five; and of Herr J. B. Obernetter, well known by his researches in photographic chemistry, on April 13, at the age of forty-seven.

A NEW GUINEA Exhibition will shortly be opened at Bremen.

MESSRS. R. FRIEDLÄNDER AND SON, of Berlin, send us the first quarterly list for 1887 of their new publications. It includes many valuable works in natural history and the exact sciences.

THE scheme for the formation of a North Sea Fisheries Institute is still under the consideration of the National Fish-Culture Association and of various local authorities, by whom efforts are being made to secure the necessary funds. It is proposed to form a Fish-Culture Station at Cleethorpes, and schools at Grimsby, and to carry out scientific observations wherever the conditions seem to be most favourable. Particular attention is to be given to the culture of the oyster and cod. A meeting has lately been held in London to advance the undertaking, and another is to take place shortly at Grimsby for the same purpose.

THE list of elements whose atomic weights have been determined with great accuracy has just received two valuable additions, for although one of them, silicon, is by no means rare in its occurrence in nature, and the other, gold, is neither among the most recently discovered of metals nor rare from the chemist's point of view, yet past determinations of the atomic weights of these important elements have resulted in leaving the subject enshrouded with considerable ambiguity. Prof. Thorpe and Mr. J. W. Young, who have recently determined the atomic weight of silicon, used for this purpose the tetrabromide $SiBr_4$, and, instead of the small quantities of material used by other experimenters, prepared upwards of half a kilogramme of this substance by passing bromine vapour over a heated mixture of pure silicon dioxide and charcoal. The product was rectified in an atmosphere of nitrogen, and portions for analysis were collected in bulbs without exposure to air; these bulbs were then broken in bottles containing pure water, and in each case the resulting turbid liquid was very slowly evaporated to complete dryness, the relation of the weight of silicon dioxide obtained to that of the tetrabromide used forming the basis of the calculations. The result of this long and difficult series of analyses fixes the atomic weight of silicon as 28·332. The instability of the salts of gold has long been a stumbling-block in the way of obtaining accurate determinations of its atomic weight, but Prof. Thorpe and Mr. A. P. Laurie have overcome this difficulty by utilising the double bromide of gold and potassium, which they prepared by digesting together pure gold, bromine, potassium bromide, and water, the salt being afterwards subjected to several recrystallisations. An unknown quantity of the pure salt was then carefully ignited, and the mixture thus obtained, of potassium bromide and gold, weighed; after removal of the potassium bromide by washing, the weight of residual gold obtained in each analysis furnished data from which one set of values averaging 196·876 was obtained. The bromine in the potassium bromide as determined by titration with silver nitrate gave a second averaging 196·837, and the weight of silver bromide formed yielded a third series of numbers, averaging 196·842. Taking Stas's value for oxygen at 15·96 the atomic weight of gold is fixed by these analyses at 196·85; but if, along with Mendelejeff, we consider oxygen 16, then gold becomes 197·28, and it is interesting to note that Mendelejeff considered the old value, 195·2, to be too low, there being no place in the periodic system for an element of this atomic weight having the properties of gold. Hence the result of the present determination has been to place gold in its proper position in the periodic classification. Prof. Krüss has just published (*Ber. Deut. Chem. Ges.* No. 2, 1887) the results of a determination of the atomic weight of gold recently made by him, according to which the probable value is 196·64. The method employed, however, was slightly different from the above, a weighed quantity of the double bromide itself being used as the basis of a portion of the analyses.

In a paper on Electric Locomotion, read before the Society of Arts on the 20th inst., Mr. Reckenzaun pointed out that in the United States and on the European continent there are dozens of electric tramways at work to the satisfaction of everybody, while we have few opportunities of testing their advantages in England. Yet England is "the home of the dynamo-machine, the country where the electromotor has found its highest development." We have been outstripped in this matter chiefly because an Act of Parliament must be obtained before electric cars can be run, and every company has to apply for it separately.

The other day M. Émile Rivière discovered a prehistoric station in the wood of Chaville, to the right of the Versailles road, in a part where there are comparatively few trees. Some flint implements and weapons were found, and a fragment of coarse pottery without ornament.

At the February meeting of the Pekin Oriental Society, Mr. Owen read a paper on animal worship amongst the Chinese. He referred at considerable length to the worship paid to the fox, weasel, hedgehog, and snake, to which at Tientsin is added the rat. The first four are called the immortals. These deified animals seem to usurp the entire attention of the people, even to the exclusion of the Buddhist and Taoist gods. Dr. Edkins quoted from the Chinese to prove that animal worship was unknown in ancient times, while Dr. Dudgeon pointed out that it was a mistake to suppose that animal worship was confined to the four animals mentioned. The horse, cow, dog, insects, dragon, lion, &c., are worshipped. In the fifth month the centipede, lizard, scorpion, frog, and snake—the five poisonous animals, as they are called—are also objects of worship. Dr. Martin disputed Dr. Edkin's theory that animal worship was unknown in ancient times because it was not mentioned by Confucius; he (Dr. Martin) believed that it existed to a much greater extent in ancient than in modern times. From the observations of other speakers it is clear that animal worship occupies a very large place in Chinese superstitious observances.

There was an interesting Geographical Exhibition in connexion with the meeting of the Deutsche Geographentag at Carlsruhe on the 13th inst. An historical department showed the development of cartography, all the exhibits being from Baden and Würtemberg. Water-colour sketches by the well-known African traveller Paul Reichard, and some fine oil sketches by the painter Hellgreve, who was sent to East Africa by the Artists' Club at Berlin, were exhibited. In the plant department were shown cotton plants found growing wild in Togoland, wild coffee and sugar-cane from Cameroons, and tobacco and various seeds from the gardens of the German East African Society.

An interesting case of "colour-hearing" was recently reported to a meeting of the Société de Psychologie Physiologique. In this case, colour-hearing was an hereditary peculiarity, transmitted from father to daughter.

The third volume of the "Grande Encyclopédie" has just been published. It is expected that thirty volumes will probably be required to complete this great work. Each volume consists of 1200 quarto pages in two columns, printed in small type.

Everyone who takes an interest in zoology is probably acquainted with the "Zoological Record," which consists of an annual volume containing a summary of the work done in the various branches of zoology. It was begun in 1865, and for the first six years was published by Mr. Van Voorst. For the last sixteen years it has been carried on by an Association of zoologists called the "Zoological Record" Association, who have received assistance in the shape of grants from the Government Fund of the Royal Society, the British Association, and the Zoological Society of London. The "Zoological Record" Association, having been lately unsuccessful in obtaining the continuance of some of these grants, and being unwilling to carry on the publication of the "Record" any longer, have agreed, upon certain conditions, to transfer their whole stock to the Zoological Society of London, who, for the future, have determined to carry on this most useful publication. The "Zoological Record" will, therefore, beginning with the volume for the present year (which will contain the record of the zoological literature of 1886), be published by the Zoological Society of London, under the management of a Committee of the Council of that Society, and will be edited by Mr. F. E. Beddard, the Society's Prosector. The "Record" will be published for the Society by Messrs. Gurney and Jackson at the former price of 30*s*. per volume. But all members of the Society will have the privilege of receiving it, including the cost of delivery, at a subscription price of 20*s*. per annum. This subscription will be due on July 1 in every year, and the privilege of subscription will be forfeited unless the amount be paid before December 1 following. The Zoological Society, having purchased the entire stock of the "Zoological Record," are now able to supply complete sets of the first twenty-two volumes at the price of 5*l*. 10*s*., that is 5*s*. per volume. Volumes of any single year can likewise be supplied at 10*s*. per volume. Learned Societies and Institutions and members of the former "Zoological Record" Association will be permitted to subscribe to the "Record" on the same conditions as are accorded to members of the Zoological Society.

It is intended to form a class, including beginners and advanced students, this summer, in the same way as last year, for the study of geology near London, to be conducted on Saturday afternoons, by Prof. H. G. Seeley, F.R.S., King's College. Applications for tickets should be made at once to the Hon. Secretary, W. W. R. May, 16 Bethune Road, Manor Road, Stoke Newington, N.

The additions to the Zoological Society's Gardens during the past week include two Rhesus Monkeys (*Macacus rhesus* ♂ ♀) from India, presented by Mr. W. F. Lock; a Common Fox (*Canis vulpes* ♂) British, presented by Mr. Isaac Bell, Jun.; a Bosch-bok (*Tragelaphus sylvaticus* ♂) from South Africa, presented by Capt. Travers; a Vulpine Phalanger (*Phalangista vulpina* ♂) from Australia, presented: two Turkey Vultures (*Cathartes aura*) from the Falkland Islands, presented by Mr. James H. Moore; a Common Viper (*Vipera berus*), British, presented by Mr. S. E Gunn; a Chinese Lark (*Melanocorypha mongolica*) from China; two Common Rheas (*Rhea americana* ♂ ♀) from the Argentine Republic, received in exchange; a Burrhel Wild Sheep (*Ovis burrhel*); two White-backed Pigeons (*Columba leuconota*) from the Himalayas; a Hodgson's Partridge (*Perdix hodgsoniæ*) from Bootan, purchased; four Long-fronted Gerbilles (*Gerbillus longifrons*), born in the Gardens.

OUR ASTRONOMICAL COLUMN

Barnard's First and Second Comets 1887.—Comet *c* 1887, discovered by Mr. Barnard on January 23, has now attained a high declination, and, though faint, may possibly be observed within the next few days. Dr. H. Kreutz gives the following ephemeris for it for Berlin midnight, derived from Dr. H. Oppenheim's elements:—

1887	R.A. h. m. s.	Decl. ° ′	log Δ	log *r*
April 27	1 12 46	65 40·4	0·4742	0·3989
29	1 21 49	65 52·7		
May 1	1 30 47	66 3·3	0·4827	0·4057
3	1 39 38	66 13·7		
5	1 48 22	66 22·5	0·4910	0·4125

Correction of ephemeris for April 15, in R.A. + 3m. 46s.; in Decl *nil*.

The second comet discovered by Mr. Barnard, viz. Comet *d* 1887, discovered February 16, is scarcely likely to be seen further. Its present brightness is but one-seventh of that which it had on March 11, and having almost exactly the same R.A as the sun it scarcely frees itself from the twilight. An ephemeris for its course throughout the month of April, based on Dr. Palisa's elements, was given by Dr. Kreutz in the *Astronomische Nachrichten*, No. 2777, and in the *Observatory* for April; but the probability of its being observed after the April full moon had passed away, except with very powerful instruments, was very slight.

Probable Re-discovery of Hesperia.—Dr. R. Luther detected a minor planet on April 11 which it appears probable is no other than the lost Hesperia, No 69, as the magnitude and motion resembled those of the missing asteroid. Dr. Luther had previously looked for the planet in vain in 1882, 1885, and in March of the present year.

The Ellipticity of Uranus.—Prof. W. Valentiner, of the Karlsruhe Observatory, writing in the *Astronomische Nachrichten*, No. 2781, states that Herr von Rebeur, observing Uranus with the 6-inch refractor of the Observatory on the evening of April 3, noticed that the disk appeared distinctly elliptical. On the following evening Prof. Valentiner himself observed the planet, and found that the direction as estimated of the major axis of the disk, the ellipticity of which was unmistakable, agreed closely with that of the assumed equatorial diameter as read off from the position-circle of the micrometer. Prof. Valentiner brings the subject forward now in the hope that those astronomers who have the command of powerful telescopes may be induced to give some attention to it.

The Washington Observatory.—It appears from *Science*, vol. ix. No. 218, that the statement (reported in last week's Nature, p. 595) that the sum of 400,000 dollars had been appropriated by Congress for the erection of a new Naval Observatory near Washington is erroneous. The amount actually available is but 100,000 dollars, with the understanding that the entire cost of the work shall not exceed 400,000 dollars.

The Paris Conference.—The same number of *Science* states that Ensign Winterhalter, of the United States Naval Observatory, had sailed for Paris, to represent the Observatory at the Photographic Conference. It is understood that Dr. Peters, of Clinton, and Mr. Rutherfurd, of New York, will also attend the Conference.

ASTRONOMICAL PHENOMENA FOR THE WEEK 1887 MAY 1–7

(For the reckoning of time the civil day, commencing at Greenwich mean midnight, counting the hours on to 24, is here employed.)

At Greenwich on May 1

Sun rises, 4h. 34m.; souths, 11h. 57m. 0·2s.; sets, 19h. 20m.; decl. on meridian, 15° 4′ N.: Sidereal Time at Sunset, 9h. 58m.

Moon (Full on May 7) rises, 11h. 27m; souths, 18h. 59m.; sets, 2h. 19m.*; decl. on meridian, 14° 0′ N.

GEOGRAPHICAL NOTES

WE are glad to know that General R. Strachey, R.E., F.R.S., has agreed to accept the presidency of the Royal Geographical Society, in succession to Lord Aberdare. The Society's honours for the present year will be conferred as follows:—The Founder's Medal to Lieut.-Colonel T. H. Holdich, R.E., for the eminent services he has rendered to geography in Afghanistan; the Patron's Medal to the Rev. George Grenfell, for the extensive explorations he has carried out during his thirteen years' residence in Africa, partly in the Cameroons country and more recently in the Congo region; the Murchison Grant to Mr. George Bourne, second in command and sole survivor of the Landsborough Expedition, which crossed the continent of Australia in 1861; the Back Premium to Sarat Chandra Das, for his researches in Tibet; the Gill Memorial to Mr. J. F. Needham, for his explorations in the Lohit Valley of the Brahmaputra. The following have been made Honorary Corresponding Members:—H.R.H. Krom Mun Damrong Rajah Nubharp, Director-General of Surveys and Minister of Public Instruction, Siam; Dr. Alfred Kirchhoff, Professor of Geography at Hallé University, and President of the Hallé Geographical Society; and Dr. E. Naumann, late Director of the Geographical and Topographical Survey of Japan.

THE paper read at the Royal Geographical Society on Monday was by General J. T. Walker, F.R.S., on the Lu River of Tibet, the Lu-Kiang, or Lu-tse-Kiang of the Chinese. This river is generally held to be the source of the Salwin, but General Walker adduced many reasons for maintaining that it is more probably that of the Irrawadi. In the course of an able paper, the result of much research, General Walker gave a most useful summary of exploration in this highly interesting hydrographical region; more particularly insisting on the value of the work of the late Abbé Krick, who ascended the Lohit in 1852, but of whom little is known in this country. General Walker made out a strong case for his position, but the leading conclusion of his valuable paper is that further exploration in this remarkable region is urgently demanded. Probably no region of the earth would yield more valuable results to scientific geography.

ACCORDING to the latest news, Mr. Stanley is well up to time in his ascent of the Congo with the Emin Pasha Expedition. He is at present on his march across country from Matadi, at the lower end of the Livingstone Falls, to Leopoldville, on Stanley Pool. It is hoped that when he reaches the Pool he will find sufficient vessels in readiness to convey his large following up the river without delay. So far the Expedition has been exceedingly fortunate.

THE statement that Baron Nordenskjold will undertake an Antarctic expedition at the expense of the King of Sweden and Mr. Oscar Dickson is, to say the least, premature. We are informed by Mr. Dickson that Baron Nordenskjold is "willing" to undertake such an expedition, but that if he does so neither the King of Sweden nor Mr. Dickson will find the money. No doubt Baron Nordenskjold would be an excellent leader for such an expedition, and as Committees have been formed both in this country and in Australia to promote Antarctic exploration, would it not be wise in them to unite their forces, and place themselves in communication with the Baron? Those who are competent to give an opinion on the subject maintain that an Antarctic expedition is much less risky than one to the other Pole. There would be no difficulty in a party wintering on some part of the Antarctic continent; a vessel could cruise round the verge of the ice during the winter and watch a favourable opening, of which immediate notice could be given to the exploring party, while a third vessel could leave New Zealand at a suitable time with additional supplies. No doubt the subject will again be brought up at the next meeting of the British Association, when it is hoped a strong and active Committee will be appointed. Baron Nordenskjold will be among the distinguished foreigners invited to the meeting, and we hope he will accept the invitation.

THE Germans continue to show great activity in the exploration of their portion of New Guinea. Freiherr von Schleinitz has recently accomplished a running survey of Huon Gulf, and besides establishing the direction of the coast-line and the positions of reefs, has laid down eight hitherto unknown harbours and discovered nine new rivers. Some of them, especially the Markham River, would form excellent routes for the exploration of the interior; the broad valley of the latter extends for miles between high ranges of mountains The south coast of Huon Gulf consists exclusively of primitive and metamorphic rocks, with older sedimentary rocks and volcanic formations. At a later date a further survey was made of the coast from Astrolabe Bay to the mouth of the Empress Augusta River, and led to the discovery of a series of bays, harbours, islands, and rivers.

M. GRIMAILO, in company with his brother, an engineer, and six Cossacks, has set out for a further exploration of the Pamir.

DR. LABONNE left Cherbourg a few days ago for a further exploration of the geysers and glaciers of Iceland.

PRELIMINARY NOTE ON THE FOSSIL REMAINS OF A CHELONIAN REPTILE, CERATOCHELYS STHENURUS, *FROM LORD HOWE'S ISLAND, AUSTRALIA*[1]

THE interesting remains of which I propose to give a brief notice in the present communication are contained in a friable sandstone (apparently formed of concreted blown sand), and they have a very recent appearance. The age of the deposit in which they are found is unknown, but it is probably Quaternary. The specimens have been for some years in the palæontological collection of the British Museum, and, for the most part, they have not yet been submitted to careful examination. But I learn that the greater number of them were long since rightly determined to be Chelonian by Mr. Davis, and set aside as such.

Several of the most important of these numerous and, in general, very fragmentary bones were originally found imbedded close together in the same block of sandstone. They consist of a great part of a pelvis, a caudal vertebra, and an imperfect skull. Of the pelvis, a right ischium and a pubis are imbedded in the rock, while an imperfect right ilium, which fits well on to the ischium, is separate; all these bones are unmistakably Chelonian. The caudal vertebra has remarkable peculiarities. It resembles an ordinary Chelonian caudal vertebra from the anterior half of the tail, in its general characters; but it is strongly opisthocœlous, the centrum having a deep cup behind and a correspondingly curved articular head in front. From the posterior part of the ventral face two stout processes diverge, and present terminal rounded facets for the rami of the large chevron bone which must have articulated with them. As a general rule, the caudal vertebræ of Chelonia are procœlous—but *Chelydra* and *Gypochelys* (perhaps also *Staurotypus* and *Platysternum*) form well-known exceptions,[2] in so far as the vertebræ behind the third and fourth are strongly opisthocœlous. In fact, the vertebra in question closely resembles the sixth or seventh of *Chelydra* or of *Gypochelys* (see Figs. 1 and 2). In the first, however, the transverse processes are very much stronger, and the pentagonal platform into which the upper surface of the neural arch expands, in place of a neural spine, is as long as the vertebra, instead of being only about half as long. The stout pre-zygapophysis of the right side is broken off, leaving only the base visible in the fossil.

---

[1] Paper read at the Royal Society, by Prof Thomas H Huxley, F R S, on March 31.

[2] The opisthocœlous character of most of the caudal vertebræ of *Chelydra* was first pointed out by Von Meyer in his description of the Œningen *Chelydra* Baur ("Osteologische Notizen," *Zool Anzeiger*, No 238, 1886) has gone fully into the question, and has pointed out the exceptional nature of their structure among the Chelonia Since the above paragraph was written, Dr Günther has kindly enabled me to examine a spirit specimen and a skeleton of *Platysternum*. The caudal vertebræ resemble those of *Chelydra*, except that the last nine are procœlous, while that between these and the more anterior opisthocœlous vertebræ is nearly flat at the ends In this, as in other respects, *Platysternum* presents characters intermediate between *Chelydra* and the ordinary *Emydæ* Prof. Cope ("Vertebrata of the Tertiary Formations of the West," 1883, p. 111) ascribes opisthocœlous caudal vertebræ to the *Bænidæ*, but no figures or descriptions of such vertebræ are given Of the opisthocœlous Chelonian vertebræ figured in Plate XXIV. of the "Report of Extinct Vertebrata obtained in New Mexico" (1887), it is expressly stated that their "correct reference cannot now be made" (p. [illegible]).

Two other caudal vertebræ, having the same structural features, occur among the detached remains, and belong, like the first, to the second fourth of the tail. Another tolerably complete vertebra, with a considerably longer centrum, corresponds very closely with a caudal vertebra of *Gypochelys* from the third fourth of the tail. In this, as in one of the foregoing vertebræ, the chevron bones are anchylosed with the centrum. I conceive, then, that there can be no doubt that the pelvic bones and these caudal vertebræ belonged to a Chelydroid Chelonian, of about the size of the largest "snapping turtles" which are met with in North America at the present day.

Primâ facie, the skull found in the same block might also be expected to be that of a Chelydroid; and, in fact, it is so. I do not base this interpretation on the Chelonian character of the upper jaw, as there are various extinct Saurian reptiles which closely approximate to Chelonia in this part of their structure. The diagnostic characters lie in the back part of the skull; and especially in the auditory region, which is altogether Chelonian. Not only so, but when this fragmentary skull is compared with that of *Chelydra*, the correspondence between the two is singularly exact (Figs. 3 and 4). In two respects, however, the fossil differs from *Chelydra* and *Gypochelys*.

(1) The roof over the temporal fossa formed by the parietal, post-frontal, and other bones, which leaves the auditory region uncovered in the recent genera,[1] extends back, beyond the occiput, in the fossil, and sends down a broad vertical rim from its margin.

(2) The upper surface of the cranial shield is, at most, rugose in the recent *Chelydridæ*; in the fossil, three strong conical processes, like horn-cores, of which the middle is the longest, are developed from its posterior and lateral region.[1]

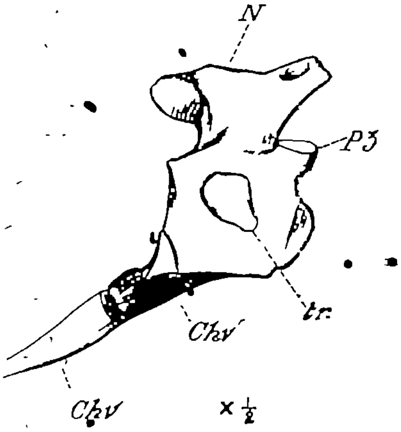

Fig. 1.—Caudal vertebra of *Ceratochelys*. *N*, platform on the neural arch; *pz*, pro-zygapophysis mutilated; *tr*, broken transverse process; *Chv'*, processes for the chevron bone; *Chv*, chevron bone.

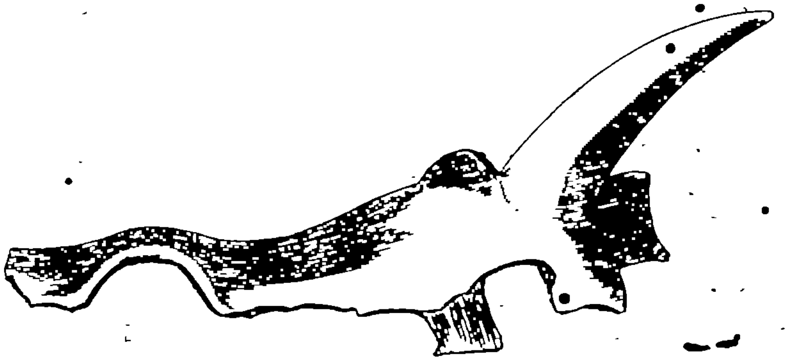

Fig. 3.

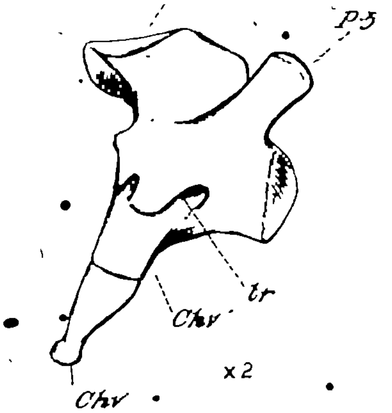

Fig. 2.—Caudal vertebra of *Chelydra*. Letters as in Fig. 1.

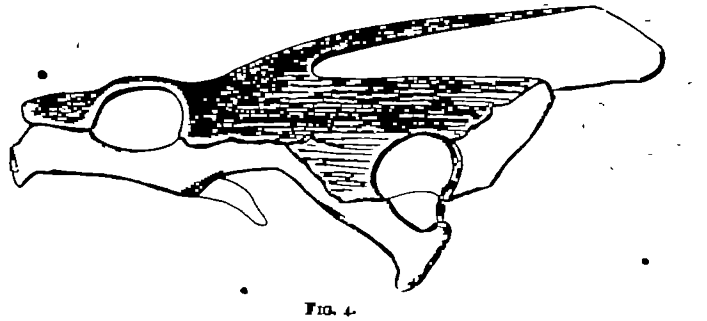

Fig. 4.

Figs. 3, 4.—Skulls of *Ceratochelys* (Fig. 3) and *Chelydra* (Fig. 4), the latter of the natural size, the former much reduced. The portion of the skull of *Chelydra* which corresponds with the fossil is shaded.

This skull is described and figured in the Philosophical Transactions for 1886 (Plate 30, Fig. 1) by Sir R. Owen, under the generic or sub-generic name of *Meiolania*, and is said to belong to a Saurian reptile closely allied to the "*Megalania prisca*" described in earlier communications. But the skull is assuredly that of the Chelydroid Chelonian to which the pelvis and caudal vertebræ belong. What *Megalania prisca* may be I do not pretend to say; but the remains which I have described can have nothing to do with any Saurian reptiles; and I propose to confer on the genus of Chelonia to which they belong the name of *Ceratochelys*.

The singular osseous caudal sheaths described by Sir R. Owen, in the same memoir, also appertain to *Ceratochelys*. They formed part of the series of remains sent to the British Museum along with the foregoing, in which none but Chelonian bones have yet been discovered; and the remains of vertebræ left in these sheaths are similar to the caudal vertebræ of the terminal fourth of the tail in the *Chelydridæ*. The snapping turtles are noted for the length and strength of the tail and for the strong, laterally-compressed, acuminated "scales" which form a crest along the median dorsal line, while others, less strongly keeled, lie at the sides of the tail. In many Chelonia, the extremity of the tail is enveloped in a continuous sheath. These and other scale-like structures in the Chelonia are usually spoken of as if they were entirely epidermal. But, a day or two ago, Dr. Günther informed me that in the Australian tortoise, *Manouria*, the great imbricated scales of the limbs contain bony scutes; and that similar scutes are to be found in *Testudo græca*. This, of course, suggested the examination of the caudal scales of *Chelydra* and *Gypochelys*; and, having been enabled by Dr. Günther's kindness to examine the caudal scales of a good-sized specimen of the latter, I have found that those of the crest contain bony scutes.[1] The bony scute corresponds very closely in form with the whole "scale," but the recurved apex of the latter is formed only by epidermal substance (Figs. 5 and 6).

---

[1] The "roof" extends much further back in *Platysternum*.

[1] It is possible that these may be dermal bones coherent with the proper cranial shield.

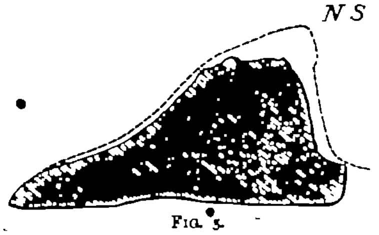

FIG. 5.

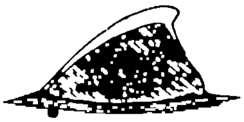

FIG. 6

FIGS. 5, 6.—Sectional views of a scute of the tail-armour of *Ceratochelys* (Fig. 5), and of one of the crest plates of *Gypochelys*, both of the natural size.

The living *Chelydra*, therefore, has a caudal armature which, in principle, is similar to that of *Ceratochelys*, but the osseous elements are relatively atrophied. There is exactly the same relation between the armour of species of living *Crocodiles* and *Alligators*, on the one hand, and those of *Jacare* and *Caiman* and the extinct *Teleosauria*, on the other. In the former, the epidermal scales remain well developed on the ventral side of the body, while the corresponding osseous scutes, fully developed in *Jacare*, *Caiman*, and *Teleosauria*, have vanished.

Among the detached fragments to which I have referred, there are remains of ribs, with their costal plates; marginal and other plates of the carapace; parts of the plastron; part of a scapula; sundry limb bones; and several of the cranial processes called "horn-cores." They all agree, so far as they can be compared, with the determination already arrived at; which, to sum it up in a few words, is that the remains of crania and caudal sheaths from Australia, hitherto referred to Saurian reptiles, under the names of *Megalania* and *Meiolania*, appertain to a hitherto unknown species of Chelonian, *Ceratochelys sthenurus*, closely allied to the living *Chelydra*, *Gypochelys*, and *Platysternum*.

The evidence of this fact offered in the present note appears to me to be conclusive, but it may be desirable hereafter to figure the parts mentioned and to describe them at length.

The interest which attaches to the discovery of this singular Chelonian arises partly from the fact that the group of Chelonia to which it belongs is wholly unrepresented in the fauna of Australia, as at present known. *Platysternum* is usually said to be found in China. Dr. Gunther, however, informs me that Upper Burmah is its proper habitat; otherwise, North America, east of the Rocky Mountains, is the nearest region in which the *Chelydridæ* are to be found. But *Chelydridæ*, and, indeed, species of the genus *Chelydra*, occur in Upper Miocene (Œningen) and in Eocene formations in Europe. Moreover, *Platychelys*, of the Upper Jurassic series of Bavaria and Switzerland, is regarded by Rutimeyer as an early form of the group.

Lord Howe's Island is about 200 miles from the nearest Australian mainland, and something like 400 miles, as the crow flies, from the Darling Downs, in which the caudal armour, which has been ascribed to *Megalania*, was found. The discovery of *Ceratochelys*, therefore, has an interesting bearing on the question of the former extension of Australia to the eastward, on the one hand; and of the possible derivation of such forms as *Ceratochelys* from Asia, on the other hand. An elevation of the sea-bottom of 6000 feet would place Norfolk Island and Lord Howe's Island on a peninsula extending from the region of the present Barrier Reef to New Zealand; and the floræ and faunæ of those islands are known to have special affinities with those of New Zealand, and none with those of Australia.

Speculations respecting the origin of the Chelonian carapace are suggested by the discovery of osseous scutes in the vertebral region of the tail, and their coalescence in *Ceratochelys* to form a sort of caudal carapace, ridged in a manner resembling that of *Chelydra* and *Platychelys*. But the consideration of these points would take me beyond the limits of the present note.

---

[1] The fact is noted by Rutimeyer (Lang and Rütimeyer, "Die Fossilen Schildkroten von Solothurn," *Denkschriften der Allg. Schweiz. Gesellschaft*, vol xxii.). The armature of the tail in *Platysternum* is for the most part arranged in zones, of four plates in each zone, but I have not yet been able to find any bone in them.

THE WORK OF THE IMPERIAL INSTITUTE[1]

I.

THE Colonial and Indian Exhibition, which owes not only its conception, but also its brilliantly successful realisation to your Royal Highness, will be pre-eminently remarkable in times to come, for having achieved many results of vital importance and highest benefit to Her Majesty's subjects in all parts of her vast realms.

The collection of all that is commercially valuable and scientifically interesting of the natural products of the great Indian Empire and of the Colonies in one Exhibition, embracing as it also did very comprehensive illustrations of the development of commerce, of the arts, and of certain industries, in the many countries beyond the seas which combine with the United Kingdom to constitute our vast Empire, afforded those at home an opportunity, surpassing all previous conception, of studying and comparing the natural history and resources of those distant lands, of which, attached though we might be individually to one or more of them by ties of friendship or of interest, the knowledge of many of us was of a very vague or partial character.

To the Colonists who visited us last year, the Exhibition has been of inestimable value, in affording them a most favourable and appropriate opportunity of becoming acquainted or renewing their old friendship with the mother country, and of examining the progress there made in industrial, educational, and commercial development; in leading to the cultivation of intimacy between Colonists from different sections of the Queen's Dominions; and in affording them invaluable opportunities of comparing the resources and state of development of their respective countries with those of other parts of Europe. No more convincing illustrations than were provided by this great Exhibition could have been conceived of the importance to the home country, to each Colony, and to India, of fostering intimate relationship and unity of action. No more encouraging proof could have been afforded of the desire of all classes of Her Majesty's subjects at home to cultivate a knowledge of those far-off countries which the enterprise and perseverance of the British, and men of British offspring, have converted into prosperous and important dominions, chiefly during the period of the Queen's reign, than was furnished by the interest which the thousands upon thousands, who came from all parts, displayed in the study of the instructive collections in the galleries at South Kensington.

It was the success of the Exhibition which led to the definite formulation of the suggestion first made by your Royal Highness in a letter addressed by you in the autumn of 1884 to the Agents-General of the Colonial Governments, that a permanent representation of the resources of the Colonies and India, and of their continually progressing development, might, with great benefit to the Empire at large, be established in this country. That the realisation of this idea upon a sufficiently comprehensive basis might constitute a worthy memorial of the accomplishment of fifty years of a wise and prosperous reign; a memorial not personal in its character excepting so far as it constituted an emblem of the love and loyalty of Her Majesty's subjects, but tending, as she would most desire, to serve the interests of the entire Empire; this had only to be pointed out by your Royal Highness to be heartily concurred in by the official representatives of the Colonies and India, who were so intimately identified with the triumphs of the recent Exhibition.

---

[1] Lecture (abridged) delivered at the Royal Institution, on Friday, April 22, by Sir Frederick Abel, C.B., F.R.S.; H.R.H. the Prince of Wales, K.G., F.R.S., Vice-Patron, in the Chair.

The Committee to whom you, Sir, intrusted the elaboration of a scheme for carrying this conception into effect, became persuaded by a careful consideration of the subject that such an Institution as your Royal Highness desired to see spring into life, to be a memorial really worthy of the Jubilee of Her Majesty's reign, and to fulfil the great purposes which you had in view, must not be confined in its objects to particular portions of Her Majesty's Dominions, but must be made thoroughly representative of the interests and of the unity of the whole Empire.

The outline of the scheme for the establishment of an Imperial Institute for the United Kingdom, the Colonies, and India, which met with the cordial approval of your Royal Highness, was necessarily concise in dealing with the very wide extent of ground which the operations of the Institute are intended to cover; but those who have carefully considered it, and rightly interpreted its proposals, have not failed to realise that it aims at very much more than the creation and maintenance of collections illustrative of the natural resources of our Colonies and of India, and of the development and present condition of the chief industries of different parts of the Empire.

One of the primary objects of the Institute will certainly be the establishment of thoroughly well selected, carefully arranged, and efficiently maintained representations of the natural products which constitute the treasures, and are emblematic of the important positions in the Empire, of those great colonial possessions which, during the fifty years of Her Majesty's reign, have, in many instances, experienced a marvellous development in extent, in commercial, social, and even in political importance.[1] The recent Exhibition not only afforded conclusive demonstration of the great interest and value to the United Kingdom which must attach to such collections if properly organised; it also served, by such illustrations as the magnificent collections of valuable woods, from nearly every colony, many quite unknown in England, and the great variety of valuable economic products from India, of the existence of which we at home had little idea, to convince us that our knowledge of the great countries which constitute the chief portion of the Empire is very limited and imperfect, and that their resources are in many directions still in the infancy of development. Our Colonial brethren cannot, on their part, fail to be greatly benefited by being thoroughly represented in a well-selected and carefully organised assemblage of illustrations of the sources of prosperity which constitute the sinews of their commerce, and upon a continued exploration and cultivation of which must depend the maintenance of their influence upon industrial and social progress. Neither can they fail to reap substantial advantages by pursuing a friendly rivalry with each other in demonstrating the advances made from time to time in the development of the resources of the respective portions of the Empire in which their lot is cast.

The hearty co-operation and important material support to which the great Colonies, through their representatives in London, pledged themselves when the scheme for the proposed Imperial Institute was in the first instance limited to this branch of the great work which it is now contemplated to accomplish, afforded conclusive evidence of their earnest desire to be in all respects thoroughly represented in the mother country, and to take their places permanently in our midst as fellow-labourers in the advancement of the prosperity of the Empire. In furtherance of this important end, a notable feature of that building which, in its character, will, it is hoped, be worthy of the momentous epoch which it is to commemorate, will be the attractions and conveniences presented by it, as a place of resort and a *rendezvous* for Colonists visiting England, and, it is also anticipated, for the important Societies which represent the Colonies and Asiatic possessions in this country, and the facilities which it will afford for reference to literature concerning the Colonies and India, for conferences on matters of common interest and value to the Colonists and those at home, for the interchange of information between the British manufacturer and those in the Colonies who are directly interested in meeting his requirements, and generally for the cultivation of intimate relations and good fellowship between ourselves and our brethren from all parts of the Empire.

The Institute will, however, not only operate actively under its own roof in promoting the cultivation of a better knowledge of the geography, natural history, and resources of our Colonies, and for the advancement of the interests of the Colonists in this country; it is also contemplated that representative collections of the natural products of the Colonies and India, carefully identified with the more elaborate collections of the head establishment, shall be distributed to provincial centres, and that the provinces shall be kept thoroughly conversant with the current information from the Colonies and India, bearing upon the interests of the commercial man, the manufacturer, and the intending emigrant.

Although the formation and maintenance up to date of collections illustrative of the development and present condition of the important industries of the Empire also forms, as I have stated, a part of the programme of the Institute, the scope of its activity in relation to industry will be of a much more comprehensive character; indeed, it is to be hoped that the work which it will achieve in furtherance of the development and progress of industries and their future maintenance in the United Kingdom at least upon a footing of equality with their conditions in the great Continental States, will be most prominent in securing to the Imperial Institute the exalted position which it should occupy as the National Jubilee Memorial of Her Majesty's reign.

There is no need for me to recall to the minds of an audience in the Royal Institution the great strides which have been made during the last fifty years in the applications of science to the purposes of daily life, to the advancement of commerce, and to the development of the arts and manufactures. Nor is it necessary to dwell upon the fact that this country is the birth-place of the majority of the great scientific and practical achievements which have revolutionised means of intercommunication, and have in other ways transformed the conditions under which manufactures, the arts, and commerce are pursued. These very achievements, of which we as a nation are so justly proud, have led, however, by many of their results, to our becoming reduced to an equality of position with other prominent nations in regard to important advantages we so long derived from the possession in this country of great material resources easy of access and application, and from the consequent pre-eminence in certain branches of the trade and industry which we so long enjoyed.

In 1852, Sir Lyon Playfair was impelled by the teaching of the preceding year's Great Exhibition to point out that "the raw material, formerly our capital advantage, was gradually being equalised in price and made available to all by the improvements in locomotion," and "that industry must in future be supported, not by a competition of local advantages, but by a competition of intellect." If this was already felt to be the state of the case six-and-thirty years ago, how much more must we be convinced of the full truth of this at the present day, by the conditions under which the British merchant and the manufacturer have to compete with their rivals on the Continent and in the United States.

It is still within the recollection of many that almost the whole world was in very great measure dependent upon Great Britain for its supplies of ordinary cast iron. Even as lately as 1871, the United States of America received from Great Britain nearly one-fifth of its total produce of pig iron; but from 1875 all importation of British iron ceased for over three years, and it was only in consequence of requirements in the States exceeding the capabilities of production, that some small demands arose in 1879, which were for some time maintained.

Within three years, however, the make of iron in the United States increased by 70 per cent., and although, since 1882, the actual make has not increased, the *capacity of production* has risen enormously, it being at present estimated at nearly 300 per cent. greater than it was in 1879. Looking nearer home, we find that the iron of France, Belgium, and Germany not only competes with ours in the open market, but that Belgian and German iron is actually imported into this country to a moderate extent.

From time to time the ground which we have lost through the development of the resources of other countries has been more than retrieved temporarily by improvements effected through the more thorough comprehension and consequent better application of the scientific principles underlying processes of manufacture, but the ultimate effect of advances of importance has not unfrequently been to improve the position, in relation to the manufactures concerned, of other nations less favourably circumstanced than Great Britain.

The history of the development of steel manufacture during the last twenty-five years affords a most instructive illustration of the fluctuations which may ensue in the value of our natural resources, and the consequent condition of one or other of our important industries, arising out of continued advances made in the application of science to the perfection or transformation of manufacturing processes, and of the stimulating effects of such fluctuations upon the exertions of those who are able to bring scientific knowledge to bear upon the solution of problems in industrial operations which entirely baffle the ordinary manufacturer. Within that period the inventions of Bessemer and of Siemens have led to the replacement of iron by steel in some of its most extensive applications. This important change in our national industry was, ere long, productive of a serious crisis therein, and for the reason that the pig iron produced from a large proportion of those ores which, from their abundance and the cheapness of their treatment, have been greatly instrumental in placing Great Britain in her high position as an iron-producing nation, could not be applied to the production of marketable steel by means of the Bessemer converter. Hence the application of this rapid steel-making process had to be chiefly restricted to particular kinds of ores, free from the impurity, phosphorus, which it was powerless to eliminate; the supplies of such ores being limited to a few districts in this country. These had to be largely supplemented by importations from other countries; nevertheless the cheapness of production and superiority in point of strength, durability, and lightness of the steel rails thus sent into the market from the Bessemer converter combined to maintain a supremacy of them over iron rails, &c., manufactured by the old puddling process from the staple ores of the country.

---

[1] Statistical statements illustrating the development of the colonies during the Queen's reign are appended.

The advantages presented by steel over the wrought iron of the puddling furnace for constructive purposes speedily became evident, and the effect of the rapid displacement of malleable iron by steel produced from ores of a particular class has been that at least 85 to 90 per cent. of the iron ores of Great Britain could no longer be applied to the production of material for rails, for ships, and for other important structures. Great has been the apprehension among the owners of those ores that the demand for iron which they can furnish could not revive, but the scientific metallurgist has successfully grappled, from more than one direction, with the great problem of restoring their commercial importance, and a simple alteration of the method of carrying out the Bessemer process has within the last few years led to really triumphant results, with the employment of those ores which before could only be dealt with by the searching operation of the old puddling furnace. A new era has thus been established in steel manufacture, there being now but very few restrictions to the application of the quick processes to iron produced from all varieties of ores. Indeed, the treatment is actually being applied profitably to the recovery of iron from the rich slag forming the refuse-product of the puddling furnace in the production of malleable iron, which before had been condemned to limited usefulness as a material for road-making. Yet another most interesting and valuable result has been achieved by this simple application of scientific knowledge. The slag or refuse-product of the so-called *basic treatment* of iron contains, in the form of phosphates of lime and magnesia, the whole of the phosphorus which it is the main function of that treatment to separate from the metal; it was soon found that the phosphoric acid was there presented in a condition as readily susceptible of assimilation by plants as it is in the valuable artificial manure known as superphosphate, this refuse-slag, simply ground up, constitutes therefore a valuable manure which already commands a ready sale at very profitable prices.

The origination of this latest advance in the development of steel manufacture dates back only nine years, and already the year's product of the basic process amounts to over 1,300,000 tons of steel. But although it is to Englishmen that the owner of iron property and the steel-maker are again indebted for these important results, and to English manufacturers that the first practical demonstration of the success of this process is due, its application has been far more rapidly elaborated upon the Continent than here; in Germany the importance of the subject was at once realised, and it is there that considerably the largest proportion of steel is produced by the basic treatment; it is in Germany also that the value of the slag for agricultural purposes has been developed, the first steps in its utilisation here being but just now taken, in Staffordshire.

I have already referred to the remarkable strides which have been made in the extension of iron manufacture in the United States; the development there of steel production has been no less marvellous, and the causes of this are evident; the resources of the country in ore and fuel are gigantic, and the systematic technical training of the people has made its influence felt upon the development of this as of every other branch of industry which our friendly rivals pursue. But it is not only in the United States that the development in the production of iron and steel has greatly increased of late years; thus, in Germany the increase in the production of pig iron alone, during the last twenty-one years, has been 237 per cent., while with us it has been 75 per cent.

Although, however, the increase in actual production of iron and steel in Great Britain has not kept pace with that of some other countries, it is satisfactory to know that our *productive power* has very greatly increased in late years, and there is probably no one branch of our industries in which we have maintained our position so satisfactorily in regard to quality of product as that of iron and steel manufacture, even though, every now and then, we have indications that in the struggle with other nations for superiority of product and for pre-eminence in continuity of progress, we have to look to our laurels.

There are, however, other important branches of industry, for a time essentially our own, the present condition of which, in this country, we cannot contemplate with equal satisfaction. Several instructive illustrations might be quoted, but I will content myself with a brief examination of one of the most interesting.

In illustrating the advances which were being made, thirty-five years ago, as demonstrated by the Exhibition of 1851, Playfair referred to the great development of the value of the evil-smelling coal-tar, which was then made to furnish the solvent liquids benzene and naphtha, and the antiseptic creosote, the residual material being utilised for pavements and for artificial fuel. The chemist little dreamt then that between 1851 and the year of the next great Exhibition, 1862, coal-tar would have become a mine of wealth equally to science, the manufactures, and to the arts, in which fresh workings have ever since continued to be opened up, and still present themselves for exploration. Hofmann, in his valuable report on the chemical products and processes elucidated by that Exhibition, dwells with the enthusiasm of the ardent worker in science upon the brilliant products obtained from coal-tar which had resulted from the labours of the scientific chemist, and had already acquired an almost national importance, although this great industry was then still in its infancy. From the year 1856, when the first colouring-matter, known as *mauve*, was discovered and manufactured by one of Hofmann's most promising young pupils, Mr. Perkin, down to the present time, the production of new coal-tar colours, or of new processes for preparing the known colours in greater purity, has progressed uninterruptedly, this industry having long since become one of the most important, and also one of the most remarkable, as illustrating by each stage of its development the direct application of scientific research to the attainment of momentous practical results.

The difficulties to be overcome before mauve could be produced upon a manufacturing scale were very great, and were only solved by a steady pursuit of scientific research, side by side with practical experiments suggested by its results. Aniline—the parent of the first coal-tar colour, a liquid organic alkali—a most fertile source of interesting and important discoveries in organic chemistry, was produced with difficulty by various methods in very small quantities, so as to be almost a chemical curiosity at the time of the discovery of mauve. Among the substances from which it had been prepared was the volatile liquid known as *benzene*, first discovered in the laboratory of this Institution in *1825* by Faraday, in the liquid products condensed from oil gas, but afterwards obtained by Mansfield, in the College of Chemistry, from coal-tar naphtha. The conversion of benzene into aniline was accomplished as a manufacturing process after many difficulties by Perkin; and within a year after the discovery of mauve by him, it was in the hands of the silk dyer. Perkin's success led other chemists at once to pursue researches in the same direction, especially in France, where the next important coal-tar colour, *magenta* or fuchsine, was obtained, by M. Verguin, the successful manufacture of which in a pure state was, however, first accomplished by English chemists. In 1861 beautiful violet and blue colours were produced, again by French chemists, but were manufactured shortly afterwards in a pure state in England.

The six years succeeding those which formed the first period (1854–62) of existence of this industry were fruitful, not only of many beautiful new dyes, first produced in England, but also of important progress made here, as well as on the Continent, in the development of the manufacture, and of our knowledge of the constitution, of the parent colours.

In the next period of six years (1868–74) another great stride was made in the coal-tar colour industry, due to important scientific researches carried out by two German chemists, Graebe and Liebermann, which led them, in the first place, to obtain an insight into the true nature of the colouring-matter of one of the most important staple dye-stuffs, namely the madder-root. They found that this colouring-matter which chemists call *alizarine* was related to *anthracene*, one of the most important solid hydrocarbons formed in the distillation of coal, a discovery which was speedily followed by the artificial formation of the madder-dye, alizarine, from that constituent of coal-tar. At first, this achievement of Graebe and Liebermann was simply of high scientific interest; but Perkin, and Graebe, and Liebermann, were not long in discovering methods by which the conversion of anthracene into the madder-dye could be accomplished on a large scale, and the manufacture of alizarine was soon most actively pursued in this country, with very momentous results, as regards the market value of the madder root. The latter has long been most extensively cultivated in Holland, South Germany, France, Italy, Turkey, and India, the consumption of madder in Great Britain having attained to an annual value of as much as 1,000,000*l.* sterling. Playfair pointed out in 1852 that important improvements had lately been attained in the extraction of the red colour or alizarine from the madder-root, but those results, most valuable at the time of the first Great Exhibition, became insignificant when once the dye was artificially manufactured from anthracene; the price paid for madder in 1865 was from 5*d.* to 8*d.* per pound, but now the equivalent in artificial madder-dye, or alizarine, of one pound of the root, can be obtained for one-halfpenny.

With the discovery of artificial alizarine the truly scientific era of the coal-tar industry may be said to have commenced, most of the commercially valuable dye-products, obtained since that time, being the result of truly theoretical research by the logical pursuit of definite well-understood reactions. The wealth of discovery in this direction made during the last thirteen years is a most tempting subject to pursue; but I must content myself with mentioning that one of the results was the production of very permanent and brilliant scarlet and red dyes, the manufacture of which has greatly reduced the market value of cochineal; that the careful study of the original coal-tar colours led to their production in a state of great purity by new and beautifully simple scientific methods; and that even the well-known vegetable colouring-matter, *indigo*, one of the staple products of India, now ranks among the colours synthetically obtained by the systematic pursuit of scientific research, from compounds which trace their origin to coal-tar.

The rapid development of the industry has also not failed to exercise a very important beneficial influence upon other chemical manufactures; thus, the distillation of tar, which was a comparatively very crude process, when, at the period of the first Exhibition, benzene, naphtha, dead-oil, and pitch were the only products furnished by it, has become a really scientific operation, involving the employment of comparatively complicated but beautiful distilling apparatus for the separation of the numerous products which serve as raw materials for the many distinct families of dyes. Very strong sulphuric acid became an essential chemical agent to the alizarine manufacturer, and, as a consequence, the so-called anhydrous sulphuric acid, the remarkable crystalline body which was for many years prepared only in small quantities from green vitriol, is now made at a low price upon a very large scale by a beautifully simple process worked out in England. The alkali and kindred chemical trades have been very greatly benefited by the large consumption of caustic soda, of chlorate of potash, and other materials used in the dye manufactures, and the application of constructive talent, combined with chemical knowledge, to the production of efficient apparatus for carrying out on a stupendous scale the scientific operations developed in the investigator's laboratory, has greatly contributed to the creation of a distinct profession, that of the chemical engineer.

One of the most beneficial results of the rapid development of the coal-tar colour industry has been its influence upon the ancient art of dyeing, which made but very slow advance until the provision of the host of brilliant, readily-applicable colours completely revolutionised both it and the art of calico-printing.

I venture to think that it will be interesting at this point to quote some words of prophecy included in Prof. Hofmann's important "Report on the Chemical Section of the Exhibition of 1862," and to inquire to what extent they have been verified. In commenting upon one of the features of greatest novelty in that world's show, the exhibition of the first dye-products derived from coal-tar, he says:—

"If coal be destined sooner or later to supersede, as the primary source of colour, all the costly dye woods hitherto consumed in the ornamentation of textile fabrics; if this singular chemical revolution, so far from being at all remote, is at this moment in the very act and process of gradual accomplishment; are we not on the eve of profound modifications in the commercial relations between the great colour-consuming and colour-producing regions of the globe? There is fair reason to believe it probable that, before the period of another decennial Exhibition shall arrive, England will have learnt to depend, for the materials of the colours she so largely employs, mainly, if not wholly, on her own fossil stores. Indeed, to the chemical mind it cannot be doubtful that in the coal beneath her feet lie waiting to be drawn forth, even as the statue lies waiting in the quarry, the fossil equivalents of the long series of costly dye-materials for which she has hitherto remained the tributary of foreign climes. Instead of disbursing her annual millions for these substances, England will, beyond question, at no distant day become herself the greatest colour-producing country in the world; nay, by the strangest of revolutions, she may ere long send her coal-derived blues to indigo-growing India, her tar-distilled crimson to cochineal-producing Mexico, and her fossil substitutes for quercitron and safflower to China, Japan, and the other countries whence these articles are now derived."

So far as concerns the displacement of madder, cochineal, quercitron, safflower, and other natural dye-materials from their positions of command in the markets of England and the world, Hofmann's predictions have been amply fulfilled, and it appeared in the earlier days of the coal-tar colour industry as though he would be an equally true prophet in regard to England becoming herself the greatest colour-producing country in the world. But, although Germany did little in the very early days of this industry, beyond producing a few of the known colours in a somewhat impure condition, many years did not elapse ere she not only was our equal in regard to quality of the dyes produced, but, moreover, had outstripped us in the quantities manufactured and in the additions made to the varieties of valuable dyes sent into the market. So far back as 1878 the value of the make of colours in England was less than one-fourth that of Germany, and even Switzerland, which, in competing with other countries industrially, is at great natural disadvantages, was not far behind us, ranking equal to France as producers. The superior position of Germany in reference to this industry may be in a measure ascribable to some defects in the operation of our Patent Laws and to questions of wages and conditions of labour; but the chief cause is to be found in the thorough realisation, by the German manufacturer, of his dependence for success and continual progress upon the active prosecution of scientific research, in the high training received by the chemists attached to the manufactories, and in the intimate association, in every direction, of systematic scientific investigation with technical work.

The young chemists whom the German manufacturer attracts to his works rank much higher than ours in the general scientific training which is essential to the successful cultivation of the habit of theoretical and experimental research, and in the consequent power of pursuing original investigations of a high order. Moreover, the research laboratory constitutes an integral part of the German factory, and the results of the work carried on by and under the eminent professors at the universities and technical colleges are closely followed and studied in their possible bearings upon the further development of the industry.

The importance attached to high and well-organised technical education in Germany is demonstrated not only by the munificent way in which the scientific branches of the universities and the technical colleges are established and maintained, but also by the continuity which exists between the different grades of education; a continuity, the lack of which in England was recently indicated by Prof. Huxley with great force.

The important part taken by the German universities in the training of young men for technical pursuits has often been dwelt upon as constituting a striking feature of contrast to our university systems. The national appreciation of the opportunities there presented for scientific training is demonstrated by the large number of students which are always working in the university laboratories,' while the expenditure of 30,000*l*. upon the physical laboratory, and 35,000*l*. upon the chemical department, of the New University of Strasburg, serves to illustrate the unsparing hand with which the resources of the country are devoted to the provision of those educational facilities which are the very life-spring of the industrial progress whence those resources are derived.

In France, higher education had been allowed to sink to a low ebb after the provincial universities had been destroyed in the great Revolution, and the University of Paris had been constituted by the first Napoleon the sole seat of high education in the country. Before the late war, matters educational were in a condition very detrimental to the position of the country among nations. There was no lack of educational establishments, but the systems and sequence of instruction lacked organisation, but since the war, France has made great efforts to replace her educational resources upon a proper footing. The provincial colleges have been re-established at a cost of 3,280,000*l*., and the organisation of industrial education has now been greatly developed, though still not on a footing of equality with that of Germany. Every large manufacturing centre has its educational establishment where technical instruction is provided, with special reference to local requirements; and, in order to render these colleges accessible to the best talent of France, more than 500 scholarships have been founded, at an annual cost of 30,000*l*. The Ecole Centrale des Arts et Manufactures, of Paris, still maintains the reputation as the great technical university of the country which it earned many years ago, and receives students from the provincial colleges, where they have passed through the essential training preliminary to the high technical education which that great institution provides.

Switzerland has often been quoted as a remarkable illustration of the benefits secured to a nation by the thoroughly organised education of its people. Far removed from the ocean, girt by mountains, poor in the mineral resources of industry, she yet has taken one of the highest positions among essentially industrial nations, and has gained victories over countries rich in the possession of the greatest natural advantages. Importing cotton from the United States, she has sent it back in manufactured forms, so as to undersell the products of the American mills. The trade of watch-making, once most important in this metropolis, passed almost entirely to Switzerland years ago; the old-established ribbon trade of Coventry has had practically to succumb before the skilled competition of Switzerland; and although she has no coal of her own, Switzerland is at least as successful as France in her appropriation of the coal-tar colour industry and her rivalry in rate of production with England, the place of its birth and development. Comparative cheapness of labour will not go very far to account for these great successes; they undoubtedly spring mainly from the thoroughly organised combination of scientific with practical education of which the entire people enjoys the inestimable benefit.

Holland furnishes another brilliant example of the success with which a nation brings the power of systematic technical education to bear in securing and maintaining industrial victories in the face of most formidable disadvantages, while the United States of America, so rich in natural resources, have long since realised the immensity of additional advantages to be gained over European nations in the war of industry by a wide diffusion and thorough organisation of technical education. So long as forty years ago the States already possessed several excellent educational institutions established upon the basis of the Continental polytechnic schools, but it was not until about fifteen years later that the country became thoroughly impressed with the great advances achieved by Germany in technical education, and that the subject was made a thoroughly national one. It is now just upon a quarter of a century ago since Congress ordained that each State should provide at least one college, having for its leading objects the diffusion of scientific instruction in its relations to the industry of the country, and decreed that public lands should be granted to the States and Territories providing such colleges. The combined effect of this State action, and of great private munificence, was a remarkably rapid development of scientific and technical education throughout the country; besides some fifty colleges, with eight or nine thousand students, which sprang out of the Land Grant Act for Industrial Education, there are now in the States about 400 other universities and colleges, in a large proportion of which efficient instruction in applied science is provided. To the useful work accomplished within a few years by these and many other highly important educational institutions, which have placed the acquisition of scientific knowledge within the reach of the very humblest, the enormous strides made by the United States in the development of home industries must unquestionably be in the main ascribed.

(*To be continued.*)

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—There are only a few alterations and additions to the usual scientific lecture-list to report, as most of the courses are in continuation of those given last term. Prof. Sylvester is to lecture on the theory of numbers; in the Chemical Department, Mr. Wyndham Dunstan lectures on organic chemistry in relation to medicine and physiology; Prof. Prestwich is to have his usual summer geological excursions; Dr. Tylor continues his exposition of the development of arts, as illustrated in the Pitt-Rivers Museum.

The Sibthorpian Professorship of Rural Economy has been filled up by the re-election of Dr. Gilbert. The Radcliffe Travelling Fellowship has been awarded to Mr. W. Overend, B.A., of Balliol. The statutes of the University Commissioners, which limited the competition for most college scholarships to candidates under nineteen, seem to be having an unfortunate, though not unexpected, effect, as several colleges have lately found it impossible to award scientific scholarships, owing to the want of sufficiently qualified candidates.

There is a good deal of strong feeling in the University with regard to the approaching appointment of a Reader in Geography, and the action of the Delegates of the University Fund in transferring a Readership from History to Geography, just after the offer of the Royal Geographical Society for a similar purpose had been refused, is the subject of much unfavourable comment. There is no thought of opposition to the study of geography, even of scientific geography, but history lecturers not unnaturally complain that the only University appointment open to them should be abolished to make a post for a lecturer in another subject.

CAMBRIDGE.—Among the seven courses on chemistry being delivered this term are lectures on gas analysis and on aromatic bodies, by Dr. S. Ruhemann. Prof. Dewar and Dr. Ruhemann also superintend laboratory practice specially directed to research.

The course given by Mr. Lyon, the Superintendent of the Mechanical Workshops, this term is on machine construction.

Mr. Langley is giving a special course on the central nervous system, with demonstrations and practical work.

Prof. Macalister's lectures this term are on the history of human anatomy. It is to be hoped that he will publish them.

Mr. M. A. Fenton is lecturing on elementary comparative osteology: Dr. Gadow on the morphology of Mammalia, recent and extinct, and on the palæontology of the Vertebrata.

Dr. Vines has a course of advanced embryology of plants, and Mr. F. Darwin is giving advanced demonstrations in the physiology of plants.

In geology, Prof. Hughes is taking the geology of the neighbourhood of Cambridge, by lectures and field excursions; Mr. Marr, foreign stratigraphy; and Mr. Roberts, the Trilobites.

Prof. Roy has classes for general pathology, morbid anatomy, and practical morbid histology, bacteriology, &c.

The lectures mentioned above are only a selection of the more interesting courses. The lists from which the above are selected announce about seventy-five courses of lectures and practical work.

Candidates for the John Lucas Walker Studentship, the holder of which must devote himself or herself to original research in pathology, should send their applications to Prof. Roy, Trinity College, Cambridge, not later than May 31 next. The Studentship is of the annual value of 250*l*., and is tenable under certain conditions for three years.

SCIENTIFIC SERIALS

The American Journal of Science, April.—Contributions to meteorology, twenty-second paper, by Elias Loomis. In this communication the author treats of areas of high pressure, their magnitude and direction of movement, and their relation to areas of low pressure. The latter subject is illustrated with a plate giving the isobars for December 15, 1882, in the northern hemisphere, and it is shown generally that the movement of areas of high pressure depends upon very different causes from that of areas of low pressure, which seem to be endowed with a power of locomotion residing within themselves. Areas of high pressure exhibit no such power, their movement seeming to depend entirely on external forces.—The faults of South-West Virginia, by John J. Stevenson. Here is given a summary of the information communicated by the author in several memoirs read before the American Philosophical Society (1880-84) on a reconnaissance made by him of the faulted region in Virginia from the Tennessee line to nearly twenty miles beyond New River, a total distance of 150 miles.—On Taconic rocks and stratigraphy, with a geological map of the Taconic regions, part 2, by James D. Dana. The general facts are here detailed which bear on the geographical distribution of the limestone and other rocks. A description is given of Williamstown, regarded as the birthplace of the Taconic system, and it is shown generally that the great quartzite formation, forming the foundation of the Palæozoic of the region, derived its material from Archæan formations of the vicinity and not from the fabled "Atlantis" as some geologists have supposed.—Irish esker drift, by G. H. Kinahan. It is pointed out that, in common with some other observers, Prof. Carvill Lewis confounds true esker drift and ridges of esker-like drift. His statement in the December number of the *American Journal of Science* that the Irish eskers appear to be adjuncts of the melting of the ice-sheets is shown to be impossible.—Physical characteristics of the northern and north-western lakes, by L. Y. Schermerhorn. The results are given of the lately completed surveys made by the United States of all the great lakes draining through the St. Lawrence to the Atlantic. The total water-area is 95,275, and the total area of the lacustrine basin over 270,000, square miles. The length of shore-line with connecting rivers is about 5400 miles, the extreme depth of Superior 1008 feet, or over 406 below sea-level, the mean annual rainfall of the whole basin 31 inches, the volume of water in the lakes about 6000 cubic miles, and the discharge of Ontario at St. Lawrence River 300,000 cubic feet per second.—Mineralogical notes from the laboratory of Hamilton College, by Albert H. Chester. Specimens are described and analysed of fuchsite, pink celestite, zinkenite, brochantite, pectolite, crystals of barite, scorodite, and bismuthite.—The topography and geology of the Cross Timbers and surrounding regions in Northern Texas, by Robert T. Hill. This wooded zone penetrating in two belts from Indian territory through the surrounding prairie southwards to 32° N. lat., is explained by the detritus of arenaceous strata which occupy well-defined horizons in the geological series, and which have been exposed by the denudation of the overlying strata.—American Jurassic mammals, by Prof. O. C. Marsh. In this paper are described the remains of several hundred individuals which have come to light since the appearance of the author's previous papers on the subject. Although fragmentary, the remains are usually well preserved, comprising the lower jaws, teeth *in situ*, various portions of the skull, vertebræ, and other parts of the skeleton. Placental as well as marsupial mammals occur in the oldest formations, whence the inference that the former do not derive from the latter evolutionally, as is supposed, but that both of these orders descend in independent lines from a common ancestor.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, March 24.—"On the Magnetisation of Iron in Strong Fields." By Prof. J. A. Ewing, University College, Dundee, and William Low.

The behaviour of iron and steel when subjected to very strong magnetising forces is a matter of considerable practical and very great theoretical interest, especially from its bearing on the molecular theory of magnetisation, which assigns an upper limit to the intensity of magnetism that a piece of iron can acquire, and even suggests that the metal may become diamagnetic under the influence of a sufficiently great force. All experiments hitherto made, by magnetising iron in the field of an electric solenoid, have shown that the intensity of magnetism, $\mathfrak{I}$, as well as the induction, $\mathfrak{B}$, is increasing with the highest values actually given to the magnetising force, $\mathfrak{H}$. It is scarcely practicable, however, to produce by the direct action of a magnetising solenoid, a field whose force exceeds a few hundreds of C.G.S. units.

In the space between the pole-pieces of a strong electro-magnet we have a field of force of much greater intensity than it is practicable to produce by the direct action of the electric current. This field is not well adapted for experiments whose object is to determine with precision the relation of magnetisation to magnetising force, on account of the distortion which it undergoes when the piece of iron to be magnetised is introduced into it. It is, however, well suited for experiments whose object is to determine how much magnetism the metal can be forced to take up.

In the authors' experiments, bobbins of Lowmoor and Swedish wrought-iron and cast-iron were magnetised by placing them between the pole-pieces of a large electro-magnet. The bobbins consisted of a short narrow central neck with conical ends. The magnetic induction in the neck was measured ballistically by means of an induction coil, consisting of a single layer of fine wire, wound on the neck; and the magnetic field in the air-space immediately contiguous to the neck was also measured by means of a second induction coil wound over the first, and of slightly greater diameter. This enabled the non-ferrous space under the inner induction coil to be corrected for, and also gave an approximation to the value of $\mathfrak{H}$, the magnetic force acting on the metal. The magnetic force varied up to about 11,080 C.G.S. units, and the highest induction observed (in a sample of Lowmoor wrought-iron) was 32,880 C.G.S. units. In some instances the magnetic induction was observed by withdrawing the bobbin; in others the bobbin was turned round suddenly so that its magnetism was reversed. The following results refer to Lowmoor wrought-iron and to cast-iron.

Lowmoor wrought-iron

Field round iron neck per sq. cm.	Magnetic induction in the metal	Current in field magnets, amperes	$\frac{\mathfrak{B} - \text{outside field}}{4\pi}$	$\frac{\mathfrak{B}}{\text{outside field}}$
3,630	24,700	1·98	1680	6·80
6,680	27,610	4·04	1670	4·13
7,800	28,870	5·81	1680	3·70
8,810	29,350	7·60	1630	3·33
9,500	30,200	11·0	1650	3·18
9,780	30,680	13·5	1660	3·14
10,360	30,830	16·2	1630	2·98
10,840	31,370	21·6	1630	2·89
11,180	31,560	26·8	1620	2·82

Cast-iron

Field round iron neck per sq. cm.	Magnetic induction in the metal	Current in field magnets, amperes	$\frac{\mathfrak{B} - \text{outside field}}{4\pi}$	$\frac{\mathfrak{B}}{\text{outside field}}$
3,900	19,660	1·97	1250	5·04
6,400	21,930	3·75	1240	3·42
7,710	22,830	5·38	1200	2·96
8,080	23,520	7·08	1230	2·91
9,210	24,580	13·15	1220	2·67
9,700	24,900	16·9	1210	2·57
10,610	25,600	22·6	1190	2·46

The magnetic force within the metal ($\mathfrak{H}$) differs from the field in the surrounding space by an amount which cannot be estimated without a knowledge of the distribution of free magnetism on the pole-pieces and conical faces of the bobbin. It appears probable that, with the dimensions of the various parts used in these experiments, the magnetic force within the metal is less, but not very greatly less, than the outside and closely neighbouring field. In the absence of any exact knowledge of $\mathfrak{H}$, it is interesting to examine the relation of $\mathfrak{B}$ to the outside field. Thus, ($\mathfrak{B}$ − outside field)/4π gives a quantity which is probably not much less than the intensity of magnetism, $\mathfrak{I}$. The values of this quantity and also of the ratio $\mathfrak{B}$/outside field for Lowmoor wrought-iron and cast-iron are stated in the tables above.

Curves are given showing the relation of $\mathfrak{B}$ to $\mathfrak{B}$/outside field for Lowmoor iron and for cast-iron, in the manner introduced by Rowland for showing the relation of $\mathfrak{B}$ to μ (the permeability). The curves have the same kind of inflection that a curve of μ and $\mathfrak{B}$ begins to have when the magnetising force is raised sufficiently high. The range through which the permeability of iron may vary is well shown by comparing the values reached here (probably in the extreme case less than 3) with the value 20,000, which was found by one of the authors in the case of a soft wire exposed to a very small magnetising force and kept at the same time in a state of mechanical vibration.

The experiments give no support to the suggestion that there is a maximum of the induction, B. The value of B capable of being reached by the method here employed depends mainly on the scale of the experiments. Larger field magnets with pole-pieces tapering to a narrow neck should yield values of B greatly in excess even of those that were observed.

Linnean Society, April 7.—Mr. William Carruthers, F.R.S., President, in the chair.—Mr Hunter J. Barron, Mr Jas. H. Dugdale, and Mr. Edwd. B. Poulton were elected Fellows of the Society.—Fresh specimens were exhibited of a pure white variety of primrose, which had been gathered, growing wild, near Biarritz, France, by Mr W. D Godolphin Osborne.—A large series of instantaneous photographs of storks nesting, &c., were exhibited for Mr. E Bidwell. These had been taken in Germany, and were specially interesting as showing the peculiar attitudes assumed in flight, &c.—Some malformed trout in an early stage of development were shown and commented on by Dr. F. Day.—A paper was read by Prof. Huxley on "The Gentians; Notes and Queries" Taking the flower as a basis, he divides the Gentianeæ into two great series, each of which is characterised by a peculiar disposition of the nectarial organs, and a gradation of forms of the corolla from the deeply cleft rotate or stellate condition, through the campanulate to the extreme infundibulate kind. In one series termed (I.) Perimelitæ, the nectarial cells are aggregated in a single or two patches; in the other series (II.) Mesomelitæ, the distinguishing characters are a zone of secreting cells encircling the ovary, or absence of such, with presence of a honey-secreting surface which may exist in the central [illegible] of the flower. He assumes, on morphological grounds, a hypothetical ancestral flower or Ur-Gentian = Haplanthe. As a starting-point, this would lead, on the one hand, to the series of Perimelitæ, with four subsidiary types; and on the other to the Mesomelitæ, also with four subsidiary types of floral structure The Perimelitæ comprise the groups:—1. Actinanthe, 2. Keratanthe, 3. Lophanthe, and 4. Stephananthe; the Mesomelitæ comprise:—1. Asteranthe, 2 Limnanthe, 3. Lissanthe, and 4. Ptychanthe. The one series appears to bear a certain progressive relation in its evolution to the leading morphological modifications of the opposite series In treating of the geographical distribution of the gentians, Prof. Huxley adopts the lines previously followed by him on animal distribution. Under (I.) Arctogea he includes Europe, Africa, Asia, and North America as far as Mexico; South Africa, Madagascar, Hindostan, and Indo-China forming a sub-province = South Arctogea; the remainder = North Arctogea. (II.) Austro-Columbia comprises South America, isthmus and islands as far north as Mexico. (III.) Australia is another province; and (IV.) New Zealand with adjoining islands. Species of the Gentianeæ are found in all these provinces, the head-quarters being North Arctogea and Austro-Columbia. The Ptychanthe are predominant in North Arctogea; the Lissanthe in South Arctogea; and Actinanthe, Lophanthe, and Lissanthe in Austro-Columbia. In Australia and New Zealand there is a paucity of species. He considers that the present distribution of the Gentianeæ is not to be accounted for by migration from any given centre, whence diffusion to their present localities. Borrowing analogy from zoological distribution, he likens the gentians to the tapirs, at present only represented in South America and the Indo-Malayan region Yet the Tapiridæ in the Middle Tertiary epoch were distributed everywhere in the intermediate areas. Though fossil remains of gentians are not yet known, Prof Huxley nevertheless suggests that in Pliocene and Miocene times their distribution may have been substantially similar to what is now extant. He further throws out the hint that, could the age of the first appearance of dipterous, hymenopterous, and lepidopterous insects provided with long haustra be indicated, we should then be in a position to guess approximately when specialisation of the types of the gentians and their ultimate distribution occurred.

Geological Society, April 6.—Prof. J. W. Judd, F.R S, President, in the chair.—The following communications were read:—On the rocks of the Malvern Hills, part 2, by Mr Frank Rutley. The details of the microscopic examination of the rocks constituted the principal part of the present paper The author concluded that the rocks of the Malvern Hills represent part of an old district consisting of plutonic and, possibly, of volcanic rocks associated with tuffs, sedimentary rocks composed mainly or wholly of eruptive materials, and grits and sandstones; that the structural planes in these rocks (sometimes certainly, at others possibly) indicate planes of stratification, and that the foliation, in many cases if not in all, denotes lamination due to deposition either in water or on land surfaces, probably more or less accentuated or altered by the movements which produced the upheavals, subsidences, and flexures prevalent in the range.—On the alleged conversion of crystalline schists into igneous rocks in County Galway, by Dr. C. Callaway.—A preliminary inquiry into the genesis of the crystalline schists of the Malvern Hills, by Dr. C. Callaway. The author's researches amongst the crystalline rocks of Connaught had suggested certain lines of investigation which had subsequently been followed out in the Malvern district. He had satisfied himself that many of the Malvern schists had been formed out of igneous rocks; but at present he limited himself to certain varieties The materials from which these schists were produced were diorite (several varieties), granite, and felsite. The metamorphism had been brought about by lateral pressure. Evidence of this was seen in the intense contortion of granite-veins and in the effects of crushing as observed under the microscope. The products of the metamorphism were divided into two groups —(1) Simple schists, or those formed from one kind of rock. (2) Injection schists, formed by the intrusion of veins, which had acquired parallelism by pressure. Veins of diorite in diorite produced *duplex diorite-gneiss*, and veins of granite in diorite originated *granite diorite-gneiss*. It was further noted that (1) generally the particular varieties of schist occurred in the vicinity of the igneous masses to which they were most nearly related in mineral composition, (2) the mineral banding of the rocks in the field was more like vein-structure than stratification. The author accepted the received view of the age of the schists. The parallel structure was clearly antecedent to the Cambrian epoch, and the occurrence of similar rocks as fragments in the Uriconian conglomerate of Shropshire seemed to indicate that the Malvernian schists were older Archæan. The reading of this paper was followed by a discussion in which the President, Mr. Teall, Dr. Hicks, Colonel McMahon, Dr. Callaway, and Mr. Rutley took part.

Entomological Society, April 6.—Dr. David Sharp, President, in the chair.—Mr. Francis Galton, F.R.S, Mr. J. H. Leech, B.A., F.L S., and Mr. G. S. Parkinson, were elected Fellows.—Mr. S Stevens exhibited specimens of *Arctia mendica*, collected in the county of Cork. The peculiarity of the Cork form of the species is that the majority of the males are as white as the female of the English form, and the typical black or English form appears to be unknown in Cork.—Mr. McLachlan exhibited a zinc box used by anglers for the purpose of keeping living flies in which he thought might be adapted to practical use in the field by entomologists.—Mr. G. T. Porritt exhibited specimens of *Hybernia progemmaria*, from Huddersfield. All the females and a large proportion of the males were of the dark variety *fuscata*, which formerly was almost unknown in Yorkshire, but which now seemed likely to replace the original type. Mr. Jenner-Weir and Lord Walsingham both remarked that the number of melanic forms appeared to be on the increase in the north, and suggested explanations of the probable causes of such increase.—Mr. Gervase F. Mathew, R.N., exhibited several new species of Rhopalocera taken by him in the Solomon Islands during the visits to those islands of H.M.S. *Espiègle* in 1882 and 1883. Amongst them were species of *Euplœa*, *Mycalesis*, *Messarus*, *Rhinopalpa*, *Cyrestis*, *Diadema*, *Parthenos*, *Pieris*, *Papilio*, &c.—Mr. E. B. Poulton exhibited a large and hairy lepidopterous larva brought from Celebes by Dr Hickson, and made remarks on the urticating properties of the hairs of the species, which were said by the natives to produce symptoms similar to those of erysipelas if the larva was handled. Lord Walsingham, Mr. McLachlan, Dr. F. A. Dixey, Mr. Jenner-Weir, Dr. Sharp, Mr. Slater, and Mr. Poulton, took part in a discussion as to whether urtication was due to the mechanical action of the hairs in the skin, or to the presence of formic acid, or some other irritant poison, in glands at the base of the hairs. There appeared to be no doubt that in some species the irritation caused by handling them was merely due to the mechanical action of the hairs.—Mr. P. Crowley exhibited a collection of Lepidoptera recently received from West Africa, including several new or undescribed species of *Mylothris*, *Diadema*, *Harma*, *Rhomaleo-*

sima, &c.—Mr. H. Goss announced the capture by Mr. G. D. Tait, at Oporto, of a specimen of *Anosia plexippus*, and remarked that, although some twenty specimens had been caught in the South of England, only two specimens had been previously recorded from the continent of Europe.—Lord Walsingham read a paper entitled "A Revision of the Genera *Acrolophus* (Poey) and *Anaphora* (Clem.)"; and exhibited about twenty new species of these and allied genera. Mr. Stainton made some remarks on the genera, and said he was glad Lord Walsingham was working at them and their allies.—Mr. Poulton read "Notes in 1886 on Lepidopterous Larvæ." In the discussion which ensued, Lord Walsingham referred at some length to instances of protective resemblance in larvæ, and alluded to the existence in certain species, especially of the genus *Melitæa*, of prothoracic glands.—Dr. F. A. Dixey remarked on the extraordinary powers of contraction which appeared to be possessed by the retractor muscle of the flagellum in *D. vinula*, and inquired whether any corresponding peculiarities of minute structure had been observed in it. The discussion was continued by Mr. G. F. Mathew, Mr. W. White, Dr. Sharp, Mr. Porritt, and others.

PARIS

Academy of Sciences, April 18.—M. Janssen, President, in the chair.—On an absolute unity of time; electric standards of time and chronoscopes of their variations, by M. Lippmann. It is shown that from the study of certain electric phenomena an absolute invariable unity of time may be obtained. The electric apparatus here described yields more accurate results than the best constructed astronomical clock. It has the further advantage of indicating, recording, and, where needed, automatically correcting, its variations of velocity.—Solar observations made at Rome during the first quarter of the year 1887, by M. Tacchini. The period of minimum activity for the spots and faculæ, as recorded in November 1886, has continued throughout the first three months of 1887. The protuberances also continued to decline during the same period.—On antipyrine, an antidote against pain, by M. Germain Sée. Antipyrine, with the formula $C_{11}H_{12}N_2O$, discovered by Knorr in 1884, is shown to be not only a good febrifuge, but also a most efficacious remedy for gout, rheumatism, and similar affections.—On the earthquake of February 23, by M. J. L. Soret. Certain derangements of the telephonic apparatus in the central office at Cannes seem to show that the violent shock which occurred at 5.50 a.m. was accompanied by strong electric discharges.—On a special circumstance connected with the production of the bicarbonate of soda, by M. Paul de Mondésir. An experiment here described shows that the carbonate of soda, combined with a single equivalent of water, scarcely absorbs carbonic acid at the ordinary temperature at all. But when it is mixed with a slight portion of dry bicarbonate the reaction on the contrary begins at once, and with an energy in direct proportion to the quantity of the bicarbonate and the thoroughness of the mixture.—Method of determining the relative value of the four unities of chemical action of the atom of carbon, by M. Louis Henry. At the base of the doctrines of organic chemistry as now understood lie the two principles of the quadrivalence of the atom of carbon, and the identity in value of its four unities of chemical action. The former is an accepted fact proved by experiment, while the latter is far from possessing the same degree of objective certainty. The author here proposes a method by means of which its truth may be rigorously determined.—Artificial reproduction of rose-red spinel (balas ruby), by M. Stanislas Meunier. The author, who has been for several years incidentally occupied with the synthesis of spinel, has lately again attacked the problem in a way quite different from his first method. He now crystallises the aluminate of magnesia, tinted a rose colour by traces of chromium, the result being a stone absolutely identical with the balas ruby of nature. The experiment here described has already been varied in several ways, yielding a series of products, such as the aluminates of zinc, iron, &c., besides secondary compounds, whose study is still in progress.—On the functions of the semicircular ducts, by M. J. Steiner. From experiments made on Crustaceans at the Zoological Station at Naples, the author shows that these organs exercise little or no influence on the locomotion of the lower animals, as supposed by Delage, Viguier, and others.—On a station of the Stone Age discovered at Chaville, by M. E. Emile Rivière. This station of Chaville lies on the skirt of the wood of like name on the right side of the road between Paris and Versailles. Here the author has just discovered a large number of flint implements of the Neolithic epoch, scrapers, knives, arrow-heads, and the like. All lay on or near the surface, and were of a more or less deep gray colour, some showing clear traces of the action of fire. They closely resemble the objects found by the author at the Neolithic station of Trou-au-Loup, Clamart, in 1884-85. Amongst them was a small fragment of black, siliceous pottery without any ornamentation, and also perfectly analogous to the pottery of the Neolithic beds in the same neighbourhood.—The members of the International Conference on Celestial Photography were present at the sitting, and were welcomed by the President in an appropriate address dwelling especially on the importance for astronomy of the photographic labours of MM. Henry, of Paris.

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH

No. 888, Vol. 35] THURSDAY, NOVEMBER 4, 1886 [Price Sixpence

Registered as a Newspaper at the General Post Office] [All Rights are Reserved

MUSGRAVE'S
NEW PATENT "ULSTER"
SLOW-COMBUSTION STOVES

Are Superior to any ever made
PERFECTLY SAFE,
HEALTHFUL,
AND DURABLE.
NO DUST OR SMELL.

GOLD MEDAL, HEALTH EXHIBITION, LONDON, 1884
SILVER MEDAL, AMSTERDAM, 1883.

DELIVERED FREE.
EASILY FIXED.

Catalogues and Estimates free from

MUSGRAVE & CO.,
LIMITED,
Ann St. Iron Works, Belfast; 97, New Bond St., London, W.; and 245, Rue de Rivoli, Paris.

UNIVERSITY OF MELBOURNE.

CHAIR OF BIOLOGY.

The University of Melbourne having created a PROFESSORSHIP of BIOLOGY, Candidates for the appointment to the new Chair are requested to address their written applications, with testimonials, to the undersigned. The duties of the Professor will be—

(1) To deliver such Lectures in Biology, and to conduct such laboratory work in that subject, as may from time to time be specified in the Statutes and Regulations of the University, or in the details of the subjects prescribed by the Professorial Board and authorised by the Council.

(2) To act as Examiner in Biology at all University Examinations.

The Professor will have the assistance of a Demonstrator.

Particulars relating to emoluments, tenure of office, &c., may be had upon application.

GRAHAM BERRY, Agent-General for Victoria.
8, Victoria Chambers, Victoria Street, Westminster, S W

SEISMOGRAPHS.

These instruments form a complete apparatus for automatically registering the motion of the ground during earthquakes. They were originally designed by Prof. J. A. Ewing for the Seismological Observatory of the University of Tokio, where some of them have been in use since 1880. The forms now offered contain many improvements in detail, suggested by experience of earthquake measurement in Japan

A fully-illustrated description and list of prices will be sent on application

THE CAMBRIDGE SCIENTIFIC INSTRUMENT CO.,
Cambridge.

GRACE'S NEW DIRECT VISION SPECTROSCOPE.

Mr. JOHN BROWNING begs to direct attention to the advantages of this very powerful, portable, and efficient Instrument, which will divide the Sodium lines or the D lines in the Solar Spectrum, and show the Rain-Band *as Separate Lines*; it is provided with a fine motion focusing arrangement, and it is applicable to every purpose for which a Direct Vision Spectroscope can be used.

Price in Morocco Leather Case, £3 8s. 6d.
Illustrated Catalogue of Spectroscopes sent post free, Sixpence.

JOHN BROWNING,
Optical and Physical Instrument Maker to H.M. Government,
68, STRAND, LONDON, W.C.

R. & J. BECK'S
NEW MICROSCOPE,
"THE STAR."

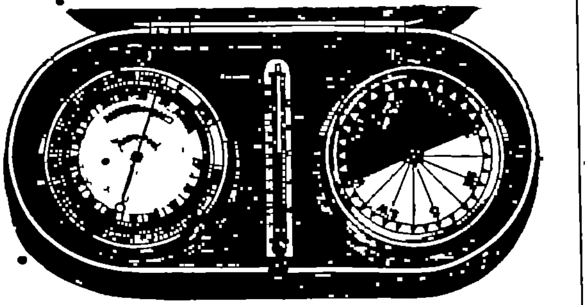
R. & J. BECK, 68, Cornhill, London, E.C.
GOLD MEDAL,
International Inventions Exhibition, 1885.

TRAVELLER'S . COMPANION.



ANEROID BAROMETER, with Altitude Scale. COMPASS, with Patent Dial, and THERMOMETER having Fahrenheit and Centigrade Scale.

Price 5 to 8 Guineas.

Illustrated Price Lists Posted Free to all Parts of the World.

NEGRETTI & ZAMBRA,

SCIENTIFIC INSTRUMENT MAKERS TO THE QUEEN,

HOLBORN VIADUCT.

BRANCHES:—45, CORNHILL; 122, REGENT STREET.

Photographers at the CRYSTAL PALACE.

N. and Z.'s Large Illustrated Catalogue, 1200 Engravings, Price 5s. 6d.

Telephone, No. 6583.

WANTED.—A Third-Grade Art Master.—Apply, PRINCIPAL, Onslow College, 183, King's Road, Chelsea, S.W.

FOR SALE.—A Good Representative Collection of Carboniferous Fossil CRUSTACEA.—No. 646, KEITH & Co., Advertising Agents, Edinburgh.

PRACTICAL GUIDE FOR FIXING HOT WATER APPARATUS for Greenhouses, Churches, Shops, Drying-rooms, Mansions, Workshops, Private and Public Baths. Illustrated. 19 stamps, post free.—J. ELDRIDGE, 54, Murray Street, Hoxton.

A METALLURGICAL CHEMIST.—A Gentleman is open to an engagement, thoroughly experienced, highest Testimonials.—Address, A. B., Mr. Trehearn, Wellington Road, Rhyl.

S. LOUIS'S SERIES OF
UNMOUNTED OBJECTS FOR THE MICROSCOPE.

11 Series of Diatoms (12 tubes in each), at 3s. each series.
46 „ Various Objects (12 to 36 in each) at 2s. ditto.

S. LOUIS'S SERIES OF *MOUNTED* OBJECTS.

43 Series, twelve (3 by 1) slides in each, at 5s. each Series. 10th Series of selected Diatoms ready.

96 Pages, New Detailed List, post free for One Stamp.

SOLE AGENT: WM. WEST, 15, Horton Lane, Bradford.

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1s. per bottle, with full instructions for use, from most Opticians, post free for 1s. 3d. from

EDWARD WARD, 249, Oxford Street, Manchester. [503

MORPHOLOGY OF THE CRUSTACEÆ.

The following interesting and rarely-observed objects, stained and mounted in balsam without pressure, 1s. 8d. each:—

The Curious Zoea of "Porcellana platycheles."
Do. of Plated Lobster, "Galathea."
Do. of Great Edible Crab, "Cancer pagurus."
Do. of Shore Crab, "Carcinus mœnas."
Megalope Stage of ditto.
Young of Hermit Crab, "Pagurus bernhardus."
Zoëa of Prawn, and Mysis Stage of ditto.

SINEL & CO., JERSEY.

Complete Catalogue of Specimens for Museum, Laboratory, and Microscope, Two Stamps. [467

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to
THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers Cephalosiphon limnias, with drawing and description. He also sent out Argulus foliaceus, Dendrosoma radians, Acineta grandis, Opercularia nutans, Limnias ceratophylli, Stephanoceros Eichhornii, Brachionus urceolaris, Hydatina senta, Cordylophora lacustris, Spongilla fluviatilis, Volvox globator; also Hydra, Amœba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s. or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

Just Published.

PROCEEDINGS OF THE SOCIETY FOR PSYCHICAL RESEARCH.

PART X. PRICE 3s.

CONTENTS.

I. Human Personality in the Light of Hypnotic Suggestion. By Frederic W. H. Myers.
II. On some Physical Phenomena commonly called Spiritualistic, witnessed by the Author. By Prof. W. F. Barrett.
Note on the above Paper, by Prof. Balfour Stewart, F.R.S.
III. Results of a Personal Investigation into the "Physical Phenomena" of Spiritualism, with some Critical Remarks on the Evidence for the Genuineness of such Phenomena. By Mrs. H. Sidgwick.
IV. The Possibilities of Mal-observation in Relation to Evidence for the Phenomena of Spiritualism. By Charles C. Massey.
Note on the above Paper, by Prof. H. Sidgwick, and further Discussion.
V. Experiments in Muscle-Reading and Thought-Transference. By Max Dessoir.
VI. On Telepathic Hypnotism, and its Relation to other Forms of Hypnotic Suggestion. By Frederic W. H. Myers.
VII. The Calculus of Probabilities applied to Psychical Research, II. By F. Y. Edgeworth.

ALSO NOW READY.

Two Vols., demy 8vo. Price 21s.

PHANTASMS OF THE LIVING.

London: TRÜBNER & CO., Ludgate Hill.

Now Ready, in One Volume, large 8vo, with 30 Illustrations, price 15s., Handsomely Bound in Cloth, Gilt Top,

OUR TEMPERAMENTS:

THEIR STUDY AND THEIR TEACHING.

A POPULAR OUTLINE.

By ALEXANDER STEWART, F.R.C.S. EDIN.

CONTENTS:

Preliminary.—General View of the Temperaments.—The Temperaments and Mind.—Scheme of the Four Pure Temperaments.—A Methodical Arrangement of their Physical and Mental Characteristics.—Observations on the Scheme.—The Nervous Temperament.—The Compound Temperaments.—Modification of the Temperament.—The Organs of the Temperaments.—The Temperaments available in—Education.—The Choice of a Profession.—The Promotion of Health.—The Use of the Word Temperament.—Word, Biographic, or Temperament Portraiture.

ILLUSTRATIONS:—A Selection from Lodge's Historical Portraits, showing the Chief Forms of Faces.

CROSBY LOCKWOOD & CO., 7, Stationers' Hall Court.

W. F. STANLEY.

Mathematical Instrument Manufacturer to H.M. Government, Council of India, Science and Art Department, Admiralty, &c.

Mathematical, Drawing, and Surveying Instruments of Every Description.

Of the Highest Quality and Finish, at the most Moderate Prices.

Illustrated Price List Post Free.

W. F. S. obtained the only Medal in the Great Exhibition of 1862 for Excellence of Construction of Mathematical Instruments, and the only GOLD MEDAL in the International Inventions Exhibition 1885 for Mathematical Work.

Address:—GREAT TURNSTILE, HOLBORN, LONDON, W.C.

MINERALS AND STONE IMPLEMENTS.

MR. BRYCE-WRIGHT begs to call the attention of his Clients and the Public to his large Series of
MINERALS AND STONE IMPLEMENTS,
from which single specimens can be selected.

Elementary Collections of Minerals, Fossils, and Rocks from £1 upwards.

N.B.—These Collections obtained the Prize Medal, 1862.

GEMS AND PRECIOUS STONES OF EVERY DESCRIPTION.

BRYCE-WRIGHT,
Mineralogist and Expert in Precious Stones,
204, REGENT STREET, LONDON, W.

MINERALS, FOSSILS, ROCKS, MICROSCOPIC OBJECTS.

RECENT SHELLS, CRUSTACEA, ECHINODERMS, CABINETS, GLASS-CAPPED BOXES, GEOLOGISTS' HAMMERS, NATURALISTS' DREDGES, &c.

THOMAS D. RUSSELL,
PRIZE MEDALLIST, HEALTH EXHIBITION.
78, NEWGATE STREET, LONDON, E.C.

HOW & CO.'S
Geological Transparencies for the Lantern.

Descriptive Catalogue on Application.

WALKER'S SPECIFIC GRAVITY BALANCE FOR ROCKS AND MINERALS.

HOW & CO.'S POCKET MICROSCOPE LAMP, 8s. 6d.

MICRO-PETROLOGY.—Sections of Pitchstones, Obsidians, Granites, Syenites, Diorites, Gabbros, Dolerites, Basalts, Tachylites, Trachytes, Andesites, Porphyrites, Rhyolites, Lavas, Ashes, Gneiss, Schists, Limestones, &c., price 1s. 6d. each.

JAMES HOW & CO., 73, FARRINGDON STREET, LONDON.

SIX PRIZE MEDALS
AWARDED FOR GEOLOGICAL COLLECTIONS.

Geological Collections especially adapted for Teaching as supplied to Science and Art Department, and used by all Lecturers and Teachers in Great Britain, &c.

New and Rare Minerals constantly arriving from all parts for selection of Single Specimens.

ROCK SECTIONS AND ROCK SPECIMENS:
The Largest Variety in England.

New Catalogues and Lists on application to—

JAMES R. GREGORY,
88, CHARLOTTE STREET, FITZROY SQUARE, LONDON.
Established 27 Years in London.

BEAUTIFUL, NEW, AND RARE MINERALS.

Mr. HENSON invites inspection of the large number of Specimens he has just received, comprising—
ARGYRODITE, ZUNYITE, Extraordinary Fine Crystals of CERUSSITE, PYROMORPHITE, DESCLOIZITE, STOLZITE, ARGENTITE, STEPHANITE, FOWLERITE, RED VANADINITE, OWAROWITE, CANADA, TOPAZES from PIKE'S PEAK, and Brilliant, Doubly-Terminated RUTILES.
SCOVILLITE, PRECIOUS OPAL, GARNIERITE, FLOS FERRI, ROSE OPAL, MOONSTONES, Very Large CHALCEDONY containing Liquid.

FOSSILS, ROCKS, and MICROSCOPIC SLIDES.
Collections, Hammers, Chisels, and Blowpipe Apparatus

PRIVATE LESSONS AND EVENING CLASSES.
CATALOGUES ON APPLICATION.

SAMUEL HENSON,
277, STRAND, LONDON,
Opposite Norfolk Street.

ZEISS MICROSCOPE STANDS in STOCK

in handsome Nickel mounted Cabinets Verified Objectives, ordinary and the new Apochromatic. List, W. HUME, Optician, Lothian Street, Edinburgh.

ROCKS, MINERALS, FOSSILS.
F. H. BUTLER,
Assoc. R. S. Mines Lond., M.A. Oxon., L.S.A. Lond., &c.,
Successor to the late R. TALLING,
180, BROMPTON ROAD, LONDON, S.W.

RECENT ACQUISITIONS:—Granulite, Devon; Schistose and ordinary Gabbro, Troctolite, Pinitiferous Elvan, and other Rocks, Cornwall; Seebachite, Embolite, Azurite, Australia; and the WRIGHT COLLECTION of Fossils.

On the 1st of every Month, price Sixpence.

THE ENTOMOLOGIST:
AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOGY.

Edited by JOHN T. CARRINGTON,
With the Assistance of

FREDERICK BOND, F.Z.S.	RICHARD SOUTH.
EDWARD A. FITCH, F.L.S.	J. JENNER WEIR, F.L.S.

F. BUCHANAN WHITE, M.D.

Contains Articles by well-known Entomologists on all Branches of the Science; on Insects injurious or beneficial to Farm or Garden; Notes on Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthly Lists of Duplicates and Desiderata.

WOODCUT ILLUSTRATIONS and occasional LITHOGRAPHED and CHROMO-LITHOGRAPHED PLATES.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

THE "HANSA,"

Published since 1864 in Hamburg, is the only independent professional paper in Germany dedicated exclusively to Maritime Objects. Essays, Critiques, Reviews, Reports, Advertisements. Strict eye kept upon the development of Maritime Affairs in every respect. Every second Sunday one Number in 4to at least; frequent supplements and drawings. Subscription at any time; preceding numbers of the year furnished subsequently. Price 12s. for twelve months. Advertisements 4d. a line widely spread by this paper; considerable abatement for 3, 6, 12 months' insertion. Business Office: Aug. Meyer and Dieckmann, Hamburg, Alterwall, 28. Edited by W. von FREEDEN M.R., Hamburg, Alexander Street, 8.

NORTH BRITISH AGRICULTURIST,

the chief Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 14s.

Offices—377, High Street, Edinburgh; and 145, Queen Victoria Street, London, E.C. Money Orders payable to C. and R. ANDERSON.

THE ENTOMOLOGIST'S MONTHLY MAGAZINE.

Price Sixpence, Monthly, 24 pages 8vo, with occasional Illustrations.
Conducted by C. G. BARRETT, J. W. DOUGLAS, R. MCLACHLAN, F.R.S., E. SAUNDERS, F.L.S., and H. T. STAINTON, F.R.S.

This Magazine, commenced in 1864, contains standard articles and notes on all subjects connected with Entomology, and especially on the Insects of the British Isles.

Subscription—Six Shillings per Volume, post free. The volumes commence with the June number in each year.

Vols. I. to VI. (strongly bound in cloth) may be obtained by purchasers of the entire set to date, at the increased price of 10s each; the succeeding vols. may be had separately or together, at 7s. each.

London: JOHN VAN VOORST, 1, Paternoster Row.

N.B.—Communications, &c., should be sent to the Editors at the above address.

Excellent Copies of the **actual, natural Handwriting,** also of **Drawings, Music,** even of **elaborate Sketches, Programmes, Plans** (up to Double-Elephant size), **Shorthand,** and **Type-Writing** are easily, quickly, and cheaply produced by the

AUTOCOPYIST

ELEMENTARY PRACTICAL PHYSICS, LESSONS IN. By Professor BALFOUR STEWART, F.R.S., and W. W. HALDANE GEE, B Sc. Crown 8vo.

Part I.—GENERAL PHYSICAL PROCESSES 6s.
Part II.—ELECTRICITY AND MAGNETISM. [In the press.
Part III.—OPTICS, HEAT, AND SOUND [In preparation.

A SCHOOL COURSE OF PRACTICAL PHYSICS. By the same Authors. [In preparation.

ON LIGHT. Being the Burnett Lectures, delivered in Aberdeen in 1883-1884. By GEORGE GABRIEL STOKES, M A., F.R.S., &c., Fellow of Pembroke College, and Lucasian Professor of Mathematics in the University of Cambridge. First Course. ON THE NATURE OF LIGHT.—Second Course. ON LIGHT AS A MEANS OF INVESTIGATION. Crown 8vo. 2s. 6d. each.
THIRD COURSE. ON THE BENEFICIAL EFFECTS OF LIGHT. [In the press.

MECHANICAL THEORY OF HEAT. By R. CLAUSIUS. Translated by WALTER R. BROWNE, M.A., late Fellow of Trinity College. Cambridge. Crown 8vo 10s. 6d.

HEAT. By P. G. TAIT, M.A., Sec. R.S.E., formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh. Crown 8vo 6s.

LIGHT; A COURSE OF EXPERIMENTAL OPTICS, CHIEFLY WITH THE LANTERN. By LEWIS WRIGHT. With 200 Engravings and Coloured Plates. Crown 8vo. 7s. 6d.

PHYSICAL ARITHMETIC. By ALEXANDER MACFARLANE, D.Sc., Examiner in Mathematics in the University of Edinburgh. Crown 8vo. 7s. 6d.

CHEMISTRY.

THE STUDY OF CHEMISTRY, AN INTRODUCTION TO By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s 6d.

COMPOUNDS OF CARBON; or, Organic Chemistry, an Introduction to the Study of By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

BIOLOGY.

THE ELEMENTS OF EMBRYOLOGY. By MICHAEL FOSTER, M.A., M.D., LL.D., Sec. R.S., Professor of Physiology in the University of Cambridge, Fellow of Trinity College, Cambridge, and the late FRANCIS M. BALFOUR, M A., LL.D., F.R.S., Fellow of Trinity College, Cambridge, and Professor of Animal Morphology in the University. Second Edition, revised. Edited by ADAM SEDGWICK, M.A., Fellow and Assistant Lecturer of Trinity College, Cambridge, and WALTER HEAPE, Demonstrator in the Morphological Laboratory of the University of Cambridge. With Illustrations. Crown 8vo. 10s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN ELEMENTARY BIOLOGY. By THOMAS HENRY HUXLEY, F.R.S., assisted by H. N. MARTIN, M.B., D Sc. New Edition, revised. Crown 8vo. 6s.

A COURSE OF ELEMENTARY PRACTICAL PHYSIOLOGY. By Prof. MICHAEL FOSTER, M.D., Sec. R S., &c., and J. N. LANGLEY, M.A., F R.S., Fellow of Trinity College, Cambridge. Fifth Edition. Crown 8vo. 7s. 6d.

AN INTRODUCTION TO THE OSTEOLOGY OF THE MAMMALIA By WILLIAM HENRY FLOWER, LL.D., F R.S., Director of the Natural History Departments of the British Museum, late Hunterian Professor of Comparative Anatomy and Physiology in the Royal College of Surgeons of England. With numerous Illustrations. Third Edition. Revised with the assistance of HANS GADOW, Ph D., M.A., Lecturer on the Advanced Morphology of Vertebrates and Strickland Curator in the University of Cambridge. Crown 8vo 10s. 6d.

AN ATLAS OF PRACTICAL ELEMENTARY BIOLOGY. By G. B. HOWES, Assistant Professor of Zoology. Normal School of Science and Royal School of Mines. With a Preface by THOMAS HENRY HUXLEY, F.R.S. Royal 4to 14s.

A COURSE OF INSTRUCTION IN ZOOTOMY (VERTEBRATA). By T. JEFFREY PARKER, B.Sc. London, Professor of Biology in the University of Otago, New Zealand. With Illustrations. Crown 8vo 8s 6d.

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, M.A., F.L.S., Professor of Botany in the University of Glasgow, and SYDNEY H. VINES, M.A., D.Sc., F.R S., Fellow and Lecturer, Christ's College. Cambridge. With a Preface by W. T. THISELTON DYER, M.A., C.M.G., F.R.S., F.L.S., Director of the Royal Gardens, Kew.
Part I.—PHANEROGAMÆ—PTERIDOPHYTA. Crown 8vo, 6s.

STRUCTURAL BOTANY, OR ORGANOGRAPHY ON THE BASIS OF MORPHOLOGY. To which are added the Principles of Taxonomy and Phytography, and a Glossary of Botanical Terms. By Professor ASA GRAY, LL.D. 8vo. 10s. 6d.

THE STUDENT'S FLORA OF THE BRITISH ISLANDS. By Sir J D. HOOKER, K.C.S.I., C.B., M D., F.R.S., D.C.L. Third Edition, revised. Globe 8vo. 10s 6d.

FIRST BOOK OF INDIAN BOTANY. By DANIEL OLIVER, F.R S., &c., Professor of Botany in University College. London, &c. With Illustrations. Extra fcap. 8vo. 6s 6d.

DOMESTIC BOTANY: An Exposition of the Structure and Classification of Plants, and their Uses for Food Clothing, Medicine, and Manufacturing Purposes. By JOHN SMITH, A L.S., &c. With Illustrations. New Issue. Crown 8vo. 12s. 6d.

EUROPEAN BUTTERFLIES, A HANDBOOK OF. By W. F. DE VISMES KANE, M A., M.R.I A., Member of the Entomological Society of London, &c. With Copper Plate Illustrations. Crown 8vo. 10s. 6d.

A LIST OF EUROPEAN RHOPALOCERA, WITH THEIR VARIETIES AND PRINCIPAL SYNONYMS. Reprinted from the *Handbook of European Butterflies.* Crown 8vo 1s.

MEDICINE.

MICRO-ORGANISMS AND DISEASE. An Introduction into the Study of Specific Micro-Organisms. By E. KLEIN, M.D., F.R S., Lecturer on General Anatomy and Physiology in the Medical School of St. Bartholomew's Hospital, London. With 121 Illustrations. Third Edition. Revised. Crown 8vo. 6s.

ANTHROPOLOGY.

ANTHROPOLOGY. An Introduction to the Study of Man and Civilisation. By E. B. TYLOR, D.C.L., F.R S. With numerous Illustrations. Crown 8vo. 7s. 6d.

PHYSIOGRAPHY AND GEOLOGY.

PHYSIOGRAPHY. An Introduction to the Study of Nature. By THOMAS HENRY HUXLEY, F.R.S. With numerous Illustrations, and Coloured Plates. New and Cheaper Edition. Crown 8vo. 6s.

CLASS-BOOK OF GEOLOGY. By ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland, and Director of the Museum of Practical Geology, London, formerly Murchison Professor of Geology and Mineralogy in the University of Edinburgh, &c. With upwards of 200 New Illustrations. Crown 8vo. 10s. 6d.

AGRICULTURE.

AGRICULTURAL CHEMICAL ANALYSIS, A Handbook of. By PERCY FARADAY FRANKLAND, Ph.D., B.Sc., F.C S., Associate of the Royal School of Mines and Demonstrator of Practical and Agricultural Chemistry in the Normal School of Science and Royal School of Mines, South Kensington Museum. Founded upon *Leitfaden für die Agricultur Chemische Analyse,* von Dr. F. KROCKER. Crown 8vo. 7s. 6d.

POLITICAL ECONOMY.

A MANUAL OF POLITICAL ECONOMY. By Right Hon. HENRY FAWCETT, F.R.S. Sixth Edition, revised, with a chapter on "State Socialism and the Nationalisation of the Land," and an Index. Crown 8vo. 12s.

A BRIEF TEXT-BOOK OF POLITICAL ECONOMY. By FRANCIS A. WALKER, M.A., Ph.D., Author of "Money," "Money in its Relation to Trade," &c. Crown 8vo. 6s. 6d.

MORAL PHILOSOPHY AND LOGIC.

THE HISTORY OF ETHICS, OUTLINES OF, FOR ENGLISH READERS. By HENRY SIDGWICK, M.A., LL.D., Knightbridge Professor of Moral Philosophy in the University of Cambridge, Author of "The Methods of Ethics," "The Principles of Political Economy," &c. Crown 8vo. 3s 6d.

THE ELEMENTS OF THE PSYCHOLOGY OF COGNITION. By the Rev. ROBERT JARDINE, B D., D.Sc. (Edin.), Ex-Principal of the General Assembly's College, Calcutta. Second Edition, revised and improved. Crown 8vo. 6s 6d.

STUDIES IN DEDUCTIVE LOGIC. By the late W. STANLEY JEVONS, LL.D., M.A., F.R.S. Second Edition. Crown 8vo. 6s.

ANCIENT GEOGRAPHY.

MANUAL OF ANCIENT GEOGRAPHY. Translated from the German of Dr. HEINRICH KIEPERT. Crown 8vo. 5s.

EVENING CLASSES IN SCIENCE.

The following among other Classes will be held during the Win Session 1886-87:—

Subjects	Lecturers
Agriculture	F. J. Lloyd, F.C.S.
Botany	Prof. Bentley, F.L.S.
Comparative Anatomy and Practical Biology	J. W. Groves.
Chemistry, Theoretical and Practical	G. S. Johnson, F.C.S.
Geology and Mineralogy	Rev. Prof. Wiltshire, M.A.
Mechanics	H. Tomlinson, B.A.
Physics, Theoretical and Practical	E. F. Herroun
Physiology	J. W. Barrett, M.B.

For Prospectuses apply to the Secretary, J. W. CUNNINGHAM, Esq., King's College, Strand, W.C

MESSRS. MACMILLAN & CO.'S SCIENCE CLASS-BOOKS.

ASTRONOMY.—POPULAR ASTRONOMY. By Sir G. B. AIRY, K.C.B., F.R.S., late Astronomer-Royal. With numerous Illustrations. Fcap 8vo. 4s. 6d.

ASTRONOMY.—ELEMENTARY LESSONS IN ASTRONOMY. By J. NORMAN LOCKYER, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 5s 6d. (Questions on, 1s 6d.)

PHYSIOLOGY.—ELEMENTARY LESSONS IN PHYSIOLOGY. By THOMAS HENRY HUXLEY, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d. (Questions on, 1s 6d.)

ANATOMY.—LESSONS IN ELEMENTARY ANATOMY. By ST. GEORGE MIVART, F.R.S. With numerous Illustrations. Fcap. 8vo. 6s 6d.

CHEMISTRY.—LESSONS IN ELEMENTARY CHEMISTRY. By Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations Fcap. 8vo. 4s. 6d. Problems adapted to the same, by Professor THORPE. With Key. 18mo. 2s.

OWEN'S COLLEGE JUNIOR COURSE OF PRACTICAL CHEMISTRY. By F. JONES. With Preface by Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations Fcap. 8vo. 2s. 6d.

QUESTIONS ON CHEMISTRY. A Series of Problems and Exercises in Inorganic and Organic Chemistry. By F JONES, F.R.S.E., F.C.S Fcap. 8vo. 3s.

CHEMICAL THEORY.—EXPERIMENTAL PROOFS OF CHEMICAL THEORY FOR BEGINNERS. By WILLIAM RAMSAY, Ph.D. Fcap 8vo. 2s. 6d.

PHYSICS.—LESSONS IN ELEMENTARY PHYSICS. By Professor BALFOUR STEWART, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s 6d. (Questions on, 2s.)

ELECTRICITY AND MAGNETISM.—ELECTRICITY AND MAGNETISM. By Professor SILVANUS THOMPSON. With numerous Illustrations. Fcap. 8vo. 4s. 6d.

ELECTRICITY AND MAGNETISM, ABSOLUTE MEASUREMENTS IN. By Professor ANDREW GRAY, M.A., F.R.S.E. Pott 8vo. 3s 6d.

ELECTRIC LIGHT ARITHMETIC. By R. E. DAY, M.A. Pott 8vo. 2s.

HEAT AND ELECTRICITY.—A COLLECTION OF EXAMPLES ON HEAT AND ELECTRICITY. By H. H. TURNER, B.A., Fellow of Trinity College, Cambridge. Crown 8vo. 2s. 6d.

UNITS AND PHYSICAL CONSTANTS. By J. D. EVERETT, M.A., D.C.L., F.R.S., F.R.S.E., Professor of Natural Philosophy, Queen's College, Belfast. Second Edition Globe 8vo. 5s.

STEAM.—AN ELEMENTARY TREATISE ON STEAM. By J. PERRY, C.E., Professor of Engineering Imperial College of Engineering, Yedo With Illustrations, Numerical Examples, and Exercises. Fcap. 8vo 4s. 6d.

SOUND.—ELEMENTARY LESSONS ON SOUND. By Dr. W. H. STONE. With Illustrations Fcap. 8vo. 3s. 6d.

ELEMENTARY SCIENCE.—NUMERICAL TABLES AND CONSTANTS IN ELEMENTARY SCIENCE. By SYDNEY LUPTON, M.A., F.C.S., F.C.L. Globe 8vo. 2s. 6d.

CHEMICAL ARITHMETIC.—CHEMICAL ARITHMETIC. With 1200 Examples. By the same Author. Second Edition. Globe 8vo. 4s 6d.

NATURAL PHILOSOPHY.—NATURAL PHILOSOPHY FOR BEGINNERS. By I. TODHUNTER, M.A., F.R.S. Fcap. 8vo. Part I.—The Properties of Solid and Fluid Bodies With Illustrations. 3s. 6d. Part II.—Sound, Light, and Heat. 3s. 6d.

PHYSICAL GEOGRAPHY.—ELEMENTARY LESSONS IN PHYSICAL GEOGRAPHY. By ARCHIBALD GEIKIE, F.R.S. With numerous Illustrations. Fcap 8vo 4s. 6d. (Questions, 1s. 6d.)

FIELD GEOLOGY.—OUTLINES OF FIELD GEOLOGY. By the same Author. With numerous Illustrations. Crown 8vo. 3s 6d.

GEOGRAPHY.—CLASS-BOOK OF GEOGRAPHY. By C. B. CLARKE, M.A., F.G.S., F.R.S. New Edition, with Eighteen Coloured Maps. Fcap. 8vo. 3s.

AGRICULTURE.—ELEMENTARY LESSONS IN THE SCIENCE OF AGRICULTURAL PRACTICE By Professor H. TANNER. Fcap 8vo. 3s. 6d.

FIELD AND GARDEN CROPS.—DISEASES OF FIELD AND GARDEN CROPS. Chiefly such as are caused by Fungi. By WORTHINGTON G. SMITH, F.L.S. Fcap 8vo. 4s. 6d.

BOTANY.—LESSONS IN ELEMENTARY BOTANY. By Professor OLIVER, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d.

POLITICAL ECONOMY.—POLITICAL ECONOMY FOR BEGINNERS. By MRS. FAWCETT. New Edition. With Questions, &c. Fcap 8vo. 2s. 6d.

ECONOMICS.—THE ECONOMICS OF INDUSTRY. By Professor A. MARSHALL and MARY P. MARSHALL. Fcap. 8vo 2s 6d.

LOGIC.—LESSONS IN LOGIC, INDUCTIVE AND DEDUCTIVE. By W. STANLEY JEVONS, LL.D., M.A., F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 3s 6d.

A TEXT-BOOK OF DEDUCTIVE LOGIC FOR THE USE OF STUDENTS.—By P. K. RAY, D.Sc. (Lond. and Edin.), Professor of Logic and Philosophy, Dacca College. Second Edition. Globe 8vo. 4s. 6d.

GEOGRAPHY.—SHORT GEOGRAPHY OF THE BRITISH ISLANDS. By J. R. GREEN and ALICE S. GREEN. With Maps. Fcap 8vo. 3s. 6d.

THE "GEBHARDT" PATENT DRAWING-BOARD.

The introduction of our Patent Supports, for Drawing or other Artists' Boards, provides for a long-felt want. Most Students have experienced great difficulty, at some time or other, in supporting their work at the proper angle, and even when this had been accomplished, to their apparent satisfaction, it has been speedily followed by failure, through the supports suddenly and unexpectedly giving way.

The arrangement is of **SIMPLE CONSTRUCTION** and **NOT LIABLE TO GET OUT OF ORDER.** It is **EASY TO ALTER TO THE REQUIRED ELEVATION**, and when closed there are no projections, but a perfectly flat surface, making it as compact and portable as those Boards which are without the Attachment.

By placing the Board on the reverse side, with the Supports projecting, it will be found the right elevation for painting, and thus serve the purpose of an Easel.

The Boards are made of the best Dry Timber, and the Supports of the best Malleable Iron.

This often happens when using the old kinds.

☞ **THEY SHOULD FIND THEIR WAY INTO EVERY SCHOOL, OFFICE, OR ARTISTS' STUDIO.**

No. 100, Deal Clamped: Size, 16 × 12 inches, 2s. 3d.; 22 × 17 inches, 3s. 3d., 40 × 27 inches, 8s. 3d.

CHEMICAL ENGINEERING.

CITY AND GUILDS OF LONDON INSTITUTE.

Course of Technical Instruction for Chemists, Manufacturers, and others, including Practice in Chemical Engineering and Physical Laboratories, under the direction of Prof. ARMSTRONG, Ph D., F.R.S.

For particulars apply at the CENTRAL INSTITUTION, Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary

CITY AND GUILDS OF LONDON INSTITUTE.

Prof. ARMSTRONG will commence a Course of Lectures on the CHEMISTRY of NITROGEN and its COMPOUNDS on January 24, 1887.

For particulars apply at the CENTRAL INSTITUTION, Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary

VICTORIA UNIVERSITY.

The Council are about to appoint EXTERNAL EXAMINERS in the following subjects :—

1. Materia Medica and Pharmacy.
2. Medicine.
3. Botany.

The appointment will be for three years, at the expiration of which the Examiner will not be eligible for re-election. For further particulars apply to the REGISTRAR. Applications must be sent in on or before December 4, 1886.

Manchester. A. T. BENTLEY, M.A., Registrar.

SCIENCE AND TECHNICAL COLLEGE, KARACHI, INDIA.

A PRINCIPAL is wanted immediately for a State-aided College of Science at Karachi. Salary, 800 rupees a month for five years certain, and afterwards 1000. £60 allowed for passage. A Graduate in Honours of a British University, who has had experience in technical education, would be preferred. The Principal will be supported by a competent Staff, but should himself be able to teach English and Pure and Applied Science. Address, stating degrees or other certificates of qualification and experience, T. B. KIRKHAM, Esq., care of Messrs. Dickeson and Stewart, 4, Queen Victoria Street, London, E.C.

MICROSCOPE AND ACCESSORIES FOR SALE.

A Ross-Trentmayer Stand made for the owner regardless of cost for scientific research.

With monocular and binocular bodies, graduated draw tube, graduated coarse and fine adjustment, vernier on main limb, swinging sub-stage, of which the circle is graduated and possesses circular and rectangular motions. Main stage graduated on circle, stage revolves by hand or rack and pinion, and is fitted with slide stop and graduated finder. Extra nose-piece fitted with Klein's quarter-plate, Sorby-Browning micro-spectroscope, with bright-spot recorder and prisms of four degrees of dispersion; Abbe's apertometer, diffraction plate, and test-slide. Eye-pieces: Pair of A, one each B, C, Kelner's C, D, E, F, Gundlach's periscopic B, Tolles' solid one-eighth, Ramsden's ocular and micrometer, centering-glass, Tolles' amplifier and adapter. Objectives: 4-inch Browning, 2-inch Powell and Lealand, 1-inch Tolles, 1-inch Browning, ½-inch Browning, ¼-inch Wray, ⅛-inch Browning wet and dry fronts, $\frac{1}{12}$-inch water-immersion Powell and Lealand—all selected with great care. Wenham's reflex illuminator (paraboloid), Wenham's diffusion illuminator, Powell and Lealand's condenser (oil immersion), Powell and Lealand's vertical illuminator, erector, unusually complete polarising apparatus, speculum in two forms, camera lucida, aperture shutter, Ross's achromatic condenser, double nose-piece, two live boxes, frog-plate, safety-stage, Swift's compressorium, stage forceps, immersion paraboloid, light-modifier, very large bull's-eye condenser—in large mahogany case with boxes for apparatus. The whole will be sold in one lot at less than half cost.

Apply to G. E. DAVIES, 301, Great Clowes Street, Manchester.

SOCIETY FOR THE PREVENTION OF HYDROPHOBIA AND REFORM OF THE DOG LAWS,

50, LEICESTER SQUARE, LONDON, W.C.

All Persons interested in the objects of this Society are invited to apply to the Honorary Secretary for Prospectus and all information.

UNIVERSITY OF MELBOURNE.

CHAIR OF BIOLOGY.

The University of Melbourne having created a PROFESSORSHIP of BIOLOGY, Candidates for the appointment to the new Chair are requested to address their written applications, with testimonials, to the undersigned. The duties of the Professor will be—

(1) To deliver such Lectures in Biology, and to conduct such laboratory work in that subject, as may from time to time be specified in the Statutes and Regulations of the University, or in the details of the subjects prescribed by the Professorial Board and authorised by the Council.

(2) To act as Examiner in Biology at all University Examinations.

The Professor will have the assistance of a Demonstrator.

Particulars relating to emoluments, tenure of office, &c., may be had upon application.

GRAHAM BERRY, Agent-General for Victoria.

8, Victoria Chambers, Victoria Street, Westminster, S.W.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to

THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers Urocentrum turbo, with sketch and description. He also sent out Argulus foliaceus, Dendrosoma radians, Acineta grandis, Cephalosiphon limnias, Limnias ceratophylli, Stephanoceros Eichhornii, Notops brachionus, Brachionus urceolaris, Cordylophora lacustris, Spongilla fluviatilis, Volvox globator; also Hydra, Amœba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T.B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s. or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

S. LOUIS'S SERIES OF UNMOUNTED OBJECTS FOR THE MICROSCOPE.

11 Series of Diatoms (12 tubes in each), at 3s. each series.

46 „ Various Objects (12 to 36 in each) at 2s. ditto.

S. LOUIS'S SERIES OF *MOUNTED* OBJECTS.

43 Series, twelve (3 by 1) slides in each, at 5s. each Series. 10th Series of selected Diatoms ready.

36 Pages, New Detailed List, post free for One Stamp.

SOLE AGENT: WM. WEST, 15, Horton Lane, Bradford.

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1s. per bottle, with full instructions for use, from most Opticians, post free for 1s. 3d. from

EDWARD WARD, 249, Oxford Street, Manchester. [503

MORPHOLOGY OF THE CRUSTACEÆ.

The following interesting and rarely-observed objects, stained and mounted in balsam without pressure, 1s. 8d. each :—

The Curious Zoea of "Porcellana platycheles."
Do. of Plated Lobster, "Galathea."
Do. of Great Edible Crab, "Cancer pagurus."
Do. of Shore Crab, "Carcinus mænas."
Megalops Stage of ditto.
Young of Hermit Crab, "Pagurus bernhardus."
Zoea of Prawn, and Mysis Stage of ditto.

A JOURNAL OF NEUROLOGY.

EDITORIAL COMMITTEE:

J C BUCKNILL, M.D., F.R.S., THOMAS BUZZARD, M D, F R.C.P, SIR J CRICHTON-BROWNE, M.D., F.R.S., DAVID FERRIER, M.D., F.R.S., J. HUGHLINGS-JACKSON, M.D., F.R.S., and JAMES ROSS, M.D., F.R C.P.

ACTING EDITOR:

A. DE WATTEVILLE, M.A., M.D., B Sc.

Contents.

ORIGINAL ARTICLES—
- On the Excitable Area of the Cortex and its Relations to the Columns of the Spinal Cord. A Reply to Prof. Horsley. By Maurice Schiff, M D.
- A Further and Final Criticism of Prof. Schiff's Experimental Demonstration of the Relation which he believes to exist between the Posterior Columns of the Spinal Cord and the Excitable Area of the Cortex. (An Answer to Prof. Schiff's "Reply" in this Issue.) By Victor Horsley, B.S., F.R S.
- Paralysis of the Movement of Convergence of the Eyes. By H. Parinaud, M.D. (Paris).
- Note on Two Newly-Described Tracts in the Spinal Cord By Charles S. Sherrington, M.B.
- The Lateral Recesses of the Fourth Ventricle; their Relation to Certain Cysts and Tumours of the Cerebellum, and to Occipital Meningocele. By J Bland Sutton, F R.C.S.
- On Certain Questions Relating to the Urinology of the Insane. By Ernest Burt.

CLINICAL CASE—
- On Sensory Epilepsy By James Anderson, M D.

CRITICAL DIGESTS—
- On the Recent Advances in our Knowledge of Tabes Dorsalis. By W. Hale White, M.D
- On the Etiology of Tabes Dorsalis. By James Petersen, M.D.

REVIEWS AND NOTICES OF BOOKS—
- Gavoy: L'Encéphale, Structure et Description Iconographique du Cerveau, du Cervelet et du Bulbe. By C. E. Beevor, M.D.

ABSTRACTS OF BRITISH AND FOREIGN JOURNALS—
- Neurological Contributions from St Bartholomew's Hospital Reports, 1874-84 By Howard H. Tooth, M B.
- Erlenmeyer: a Study of the Disturbances of Co-ordination in Children. By J. A. Ormerod, M.D

MACMILLAN & CO., LONDON

SWAN SONNENSCHEIN & CO.'S LIST

TEXT-BOOK OF PRACTICAL BOTANY: a Manual for Students. Edited from the work of Prof W. STRASBURGER, by Prof. W. HILLHOUSE, M.A, of the Mason College, Birmingham. Illustrated by a large number of New Woodcuts 8vo. [*In a few days.*

This day, with 100 Woodcuts and 50 Diagrams, 6s.

LIFE-HISTORIES of PLANTS. With an Introductory Section on the Comparative Study of Plants and Animals By Prof. D. McALPINE.

A STAR ATLAS. By the Rev. T. H. Espin. Twelve Simple Star Maps and Text. 4to, cloth, 1s. 6d.

"We would advise those who desire to gain some knowledge of the wonders and beauties of the Heavens to begin their studies with the aid of Mr. Espin's Star Atlas"—*Field.*

FOURTH DIMENSION TRACTS

By C. HOWARD HINTON, M A.

8vo, Illustrated, each 1s; or in 1 vol., bound as "Scientific Romances," 6s.

GHOSTS EXPLAINED.

1. WHAT IS THE FOURTH DIMENSION? By C. H. HINTON, M.A. Crown 8vo, 1s.

"A short treatise of admirable clearness . . . Mr. Hinton brings us panting but delighted, to at least a momentary faith in the Fourth Dimension, and upon the eye of this faith there opens a vista of interesting problems. . . . His pamphlet exhibits a boldness of speculation, and a power of conceiving and expressing even the inconceivable, which rouses one's faculties like a tonic."—*Pall Mall.*

THE MYSTERY OF PLEASURE AND PAIN.

2. THE PERSIAN KING; or, the Law of THE VALLEY. By C. H. HINTON, M.A. Crown 8vo, 1s.

"A very suggestive and well-written speculation by the inheritor of an honoured name."—*Mind.*

"Will arrest the attention of the reader at once"—*Knowledge.*

3. CASTING OUT THE SELF. [*This day*

4. A PLANE WORLD. [*This day.*

5. A PICTURE OF OUR UNIVERSE. [*This day.*

THE FIRST THREE YEARS of CHILDHOOD. By BERNARD PEREZ. With Introduction by Prof. JAMES SULLY, M A, &c. Crown 8vo, 4s. 6d.

"A rich mine of facts, and the fullest monograph on its subject."—*Educational Times.*

SWAN SONNENSCHEIN, LOWREY, & CO.,

SIAM. COUTTS TROTTER.

Edinburgh: ADAM & CHARLES BLACK.

PUBLISHED BY J. & A. CHURCHILL.

With numerous Lithographic Plates (Plain and Coloured), Price 10*s.* each Number.

THE QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE.

Edited by E. RAY LANKESTER, M.A., LL.D., F.R.S., Fellow of Exeter College, Oxford, and Jodrell Professor of Zoology in University College, London.

With the co-operation of W. T. THISELTON DYER, M.A., C.M.G., F.R.S., Director of the Royal Gardens, Kew; E. KLEIN, M.D., F.R.S., Joint-Lecturer on General Anatomy and Physiology in the Medical School of St. Bartholomew's Hospital, London; H. N. MOSELEY, M.A., LL.D., F.R.S., Linacre Professor of Human and Comparative Anatomy in the University of Oxford; and ADAM SEDGWICK, M.A., F.R.S., Fellow and Assistant Lecturer of Trinity College, Cambridge.

CONTENTS OF No. CV. (VOL. XXVII. PART 1), AUGUST.

Memoirs:

The Anatomy of the Madreporaria, II. By G. Herbert Fowler, B.A. Keble College, Oxon., Berkeley Fellow of the Owens College, Manchester. (With Plate.)

On the Formation of the Germinal Layers in Chelonia. By K. Mitsukuri, Ph.D., Professor of Zoology, and C. Ishikawa, Assistant in Zoology, University of Tokio, Japan. (With Four Plates.)

On the Structure and Development of the Reproductive Elements in *Myxine glutinosa*, L. By J. T. Cunningham, B.A., Fellow of University College, Oxford, and Superintendent of the Scottish Marine Station. (With Two Plates.)

Studies on Earthworms, No. II. By William Blaxland Benham, B.Sc., Demonstrator in the Zoological Laboratory of University College, London. (With Two Plates.)

On *Dinophilus gigas*. By W. F. R. Weldon, M.A., Fellow of St. John's College, Cambridge; Lecturer on Invertebrate Morphology to the University. (With Plate.)

CONTENTS OF No. CVI. (VOL. XXVII. PART 2), OCTOBER.

Memoirs:

The Development of the Mole (*Talpa europea*). Stages E to J. By Walter Heape, M.A., Resident Superintendent of the Plymouth Laboratory of the Marine Biological Association of the United Kingdom. (With Three Plates.)

On the Presence and Structure of the Pineal Eye in Lacertilia. By W. Baldwin Spencer, B.A., Fellow of Lincoln College, Oxford; Demonstrator of Comparative Anatomy in the University Museum, Oxford. (With Seven Plates.)

On the Life-History of Pedicellina. By Sidney F. Harmer, B.A., B.Sc., Fellow of King's College, Cambridge, and of University College, London. (With Two Plates.)

Dr. Dohrn's Inquiries into the Evolution of Organs in the Chordata. By J. T. Cunningham, B.A., F.R.S.E.

Review:

Patten on the Eyes of Mollusks and Arthropods.

Fifth Edition, Revised and Enlarged, with 90 Engravings, 8vo, 16*s.*, now ready.

A SYSTEMATIC HANDBOOK OF VOLUMETRIC ANALYSIS;

or, the Quantitative Estimation of Chemical Substances by Measure, applied to Liquids, Solids, and Gases. Adapted to the Requirements of Pure Chemical Research, Pathological Chemistry, Pharmacy, Metallurgy, Manufacturing Chemistry, Photography, &c., and for the Valuation of Substances used in Commerce, Agriculture, and the Arts. By FRANCIS SUTTON, F.C.S., F.I.C.

Vol. II., Second Edition, Revised and Enlarged, 8vo, 17*s.* 6*d.*, now ready.

COMMERCIAL ORGANIC ANALYSIS. By Alfred H. Allen,

F.I.C., F.C.S.

Contents:—Fixed Oils, Lard, Tallow, Butter, Waxes, Lubricating Oils, Fatty Acids, Soaps, Glycerin, Hydrocarbons, Shale Oil, Coal Tar, Asphalt, Petroleum, Kerosene, Paraffin, Essential Oils, Turpentine, Resins, Rosin Oil, Benzols and Naphthas, Naphthalene, Anthracene, Carbolic Acid, Carbolic Powders, Creosote Oils, Creosote, &c., &c.

Vol. I. (price 14*s.*) contains Alcohols, Ethers, and other Neutral Alcoholic Derivatives, Sugars, Starch and its Isomers, Vegetable Acids, &c., &c.

Vol. III., completing the work, is in preparation.

Crown 4to, half-Persian, £1 12*s.* 6*d.*, now ready.

HARVEY'S MANUSCRIPT LECTURES. Edited by a Committee of

the Royal College of Physicians of London.

⁎ These original Lectures of William Harvey, delivered by him before the Royal College of Physicians in and after 1616, were re-discovered in the British Museum in the year 1877. A facsimile reproduction, accompanied by an interleaved transcript, is now offered to the profession. The facsimile, comprising 97 leaves, has been executed by the Autotype Company, whose reputation affords guarantee of thoroughly accurate work, while the transcript (without which the lectures could not be deciphered by the ordinary reader, however well versed he might be in Latin) is by Mr. Edward Scott, M.A., Assistant Keeper of MSS., British Museum.

Sixth Edition, Crown 8vo, 10*s.* 6*d.*, now ready.

HANDBOOK OF HYGIENE AND SANITARY SCIENCE. By

GEO. WILSON, M.D., F.R.S.E., Medical Officer of Health for Mid-Warwickshire.

With 230 Original Drawings by the Author, Crown 8vo, 15*s.*, now ready.

THE NORMAL AND PATHOLOGICAL HISTOLOGY OF THE

HUMAN EYE AND EYELIDS. By C. FRED. POLLOCK, M.D., F.R.C.S.E., F.R.S.E., Surgeon for Diseases of the Eye, Anderson's College Dispensary, Glasgow.

"The drawings are done by a skilful hand, and will be recognised as unusually faithful. . . . The book is a most welcome addition to our special literature, and supplies a real want."—*Ophthalmic Review.*

A MANUAL OF CHEMISTRY. By Henry Watts, B.A., F.R.S.

Vol. I. PHYSICAL AND INORGANIC CHEMISTRY. Crown 8vo, 9*s.* Vol. II. ORGANIC CHEMISTRY. Edited by WILLIAM A. TILDEN, D.Sc., F.R.S. Crown 8vo, 10*s.*

⁎ These two volumes are based on the well-known Manual of Fownes, and form the Thirteenth Edition of that work.

LONDON: J. & A. CHURCHILL, 11, NEW BURLINGTON STREET.

FOURTH EDITION, Revised and Considerably Enlarged.

SPECTRUM ANALYSIS.

SIX LECTURES DELIVERED IN 1868 BEFORE THE SOCIETY OF APOTHECARIES OF LONDON.

BY

SIR HENRY E. ROSCOE, LL.D., F.R.S.,
Professor of Chemistry in the Owens College, Victoria University, Manchester.

FOURTH EDITION, REVISED AND CONSIDERABLY ENLARGED BY THE AUTHOR AND

ARTHUR SCHUSTER, Ph.D., F.R.S.,
Professor of Applied Mathematics in Owens College, Victoria University.

With Appendices and numerous Illustrations and Plates. Medium 8vo. 21*s.*

NATURE says:—"This is a fourth edition of a well-known book, and the joint authors have evidently taken some trouble to bring the present edition up to date."

The *Cambridge Review* says:—"The result is that the book is the best we know both for the beginner in the subject and the advanced student."

The *Scotsman* says:—"The additional information required to bring the book abreast of the present level of knowledge and ascertained fact has for the most part been embodied in a series of appendices attached to each lecture. Equipped with six plates and upwards of a hundred diagrams, the work is valuable alike to the general reader and to the systematic student."

The *Leeds Mercury* says:—"There is no need to intimate to students of physical science that Roscoe's 'Spectrum Analysis,' as it now comes before us, is fully abreast of the most recent phases of this rapidly-growing subject, and is not less deserving of their full confidence than were the earlier editions. In this, which is the fourth edition, the lectures have been wholly revised and almost entirely re-written, and no effort has been spared to bring them up to date in all essential points."

The *Literary World* says:—"'Spectrum Analysis' may be read not only by experts as a work of standard value, but also by that portion of the thoughtful public that cares for a lucid explanation of one of the most interesting, though, at the same time, one of the most intricate, branches of physical science."

BIUNIAL	£7	10	0
TRIPLE	15	15	0

WATSONS' NEW SCREEN STAND, an immense convenience to Exhibitors; exceedingly light and compact to carry, easy to erect, perfectly rigid when set up, and holds the Screen tightly stretched Price for 9-feet Screen, 35*s*., 10-feet, 37*s*. 6*d*.; 12-feet, £2 2*s*. 0*d*.

An Illustrated Catalogue of Magic Lanterns and Apparatus, and List of large and varied Stock of Slides, post free on application.

WATSON & SONS' NEW HISTOLOGICAL MICROSCOPE.

FREE ON APPLICATION.

ILLUSTRATED CATALOGUE
OF
MICROSCOPES
AND
APPARATUS.

Classified List of 40,000 First-class Microscopic Objects.

A thoroughly first-rate Microscope at an extremely moderate price. It is mounted on an exceedingly firm brass foot, has sliding body for coarse adjustment, draw-tube, plane and concave mirrors, tube fitting of universal size for under-stage apparatus, with special arrangement for oblique illumination, set of diaphragms, with pin-hole stop, and is fitted with WATSON & SON'S improved form of fine adjustment, as supplied to their best instruments, which is perfectly free from all lateral motion, even when working with the highest powers, and permits of the greatest possible delicacy of adjustment. The entire instrument is finished in the very best manner, and is unequalled in value at the price.

Microscope, as illustrated, with "C" eye-piece, ¼ and 1 inch first-class English objectives, giving a range of amplification from 75 to 700 diameters, in mahogany cabinet, price

£4 15s. 0d.

GOLD MEDAL,
International Inventions Exhibition, 1885.

SEISMOGRAPHS.

These instruments form a complete apparatus for automatically registering the motion of the ground during earthquakes. They were originally designed by Prof. J. A. Ewing for the Seismological Observatory of the University of Tokio, where some of them have been in use since 1880. The forms now offered contain many improvements in detail, suggested by experience of earthquake measurement in Japan.

A fully-illustrated description and list of prices will be sent on application.

THE CAMBRIDGE SCIENTIFIC INSTRUMENT CO.,
Cambridge.

S. LOUIS'S SERIES OF
UNMOUNTED OBJECTS FOR THE MICROSCOPE.

ELECTRICAL ENGINEERING.

CITY AND GUILDS OF LONDON INSTITUTE.

The Courses of Technical Instruction at the Central Institution, Exhibition Road, S.W., are open to persons desirous of studying any branch of ELECTRICAL ENGINEERING. The Instruction, under the general direction of Prof. AYRTON, F.R.S., comprises Lectures and Practice in the Laboratories and Dynamo-Room. For particulars apply at Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

DYNAMO-ELECTRIC MACHINERY.

A Special Course of PRACTICAL DEMONSTRATIONS in the TESTING of the POWER and EFFICIENCY of DYNAMOS and MOTORS will be given by Prof. AYRTON F.R.S., at the CENTRAL INSTITUTION of the CITY and GUILDS of LONDON INSTITUTE, commencing on FRIDAY, February 4, at 5 p.m. For particulars apply at Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

CHEMICAL ENGINEERING.

CITY AND GUILDS OF LONDON INSTITUTE.

Course of Technical Instruction for Chemists, Manufacturers, and others, including Practice in Chemical Engineering and Physical Laboratories, under the direction of Prof. ARMSTRONG, Ph.D., F.R.S.

For particulars apply at the CENTRAL INSTITUTION, Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

CITY AND GUILDS OF LONDON INSTITUTE.

Prof. ARMSTRONG will commence a Course of Lectures on the CHEMISTRY of NITROGEN and its COMPOUNDS on January 24, 1887.

For particulars apply at the CENTRAL INSTITUTION, Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

VICTORIA UNIVERSITY.

The Council are about to appoint EXTERNAL EXAMINERS in the following subjects:—

1. Materia Medica and Pharmacy.
2. Medicine.
3. Botany.

The appointment will be for three years, at the expiration of which the Examiner will not be eligible for re-election. For further particulars apply to the REGISTRAR. Applications must be sent in on or before December 4, 1886.

Manchester. A. T. BENTLEY, M.A., Registrar.

ASTRONOMICAL TELESCOPE FOR SALE.—8½-inch Silvered-Glass Speculum TELESCOPE, Azimuth Stand, Wheel and Handles, &c., complete.—Price and particulars to No. 622, KEITH & Co., Advertising Agents, Edinburgh.

BRITISH STALK-EYED CRUSTACEA

(Crabs, Lobsters, and Shrimps).—Collection containing almost all Species and about 300 Specimens, perfectly prepared and in splendid order. The whole inclosed in a MAHOGANY CABINET of twelve large glazed drawers, especially made to suit this Collection. Well suited for a Country Museum. Also two Ten-Drawer Polished Deal Cabinets, containing 765 Species of British and Foreign Shells (about 1300 Specimens), 33 Red-Crag Fossils (200 Specimens), 100 Fossil Teeth (170 Specimens), and 60 Birds' Eggs (100 Specimens)—mostly inclosed in Rectangular Glass-capped Boxes, all named. Owner going abroad, so must part with this valuable Collection. £60, or offers.—Address ALPHA, Beech Cottage, 2, Wellington Road, Bow, London, E.

MORPHOLOGY OF THE CRUSTACEÆ.

The following interesting and rarely-observed objects, stained and mounted in balsam without pressure, 1*s.* 6*d.* each:—

The Curious Zoea of "Porcellana platycheles."
Do. of Plated Lobster, "Galathea."
Do. of Great Edible Crab, "Cancer pagurus."
Do. of Shore Crab, "Carcinus mænas."
Megalope Stage of ditto.
Young of Hermit Crab, "Pagurus bernhardus."
Zoëa of Prawn, and Mysis Stage of ditto.

SINEL & CO., JERSEY.

FOURTH EDITION, Revised and Considerably Enlarged.

SPECTRUM ANALYSIS.

SIX LECTURES DELIVERED IN 1868 BEFORE THE SOCIETY OF APOTHECARIES OF LONDON.

BY

SIR HENRY E. ROSCOE, LL.D. F.R.S.,

Professor of Chemistry in Owens College, Victoria University, Manchester.

FOURTH EDITION, REVISED AND CONSIDERABLY ENLARGED BY THE AUTHOR AND

ARTHUR SCHUSTER, Ph.D., F.R.S.,

Professor of Applied Mathematics in Owens College, Victoria University.

With Appendices and numerous Illustrations and Plates. Medium 8vo. 21s.

NATURE says:—"This is a fourth edition of a well-known book, and the joint authors have evidently taken some trouble to bring the present edition up to date."

The *Cambridge Review* says:—"The result is that the book is the best we know both for the beginner in the subject and the advanced student."

The *Scotsman* says:—"The additional information required to bring the book abreast of the present level of knowledge and ascertained fact has for the most part been embodied in a series of appendices attached to each lecture. Equipped with six plates and upwards of a hundred diagrams, the work is valuable alike to the general reader and to the systematic student."

The *Leeds Mercury* says:—"There is no need to intimate to students of physical science that Roscoe's 'Spectrum Analysis,' as it now comes before us, is fully abreast of the most-recent phases of this rapidly-growing subject, and is not less deserving of their full confidence than were the earlier editions. In this, which is the fourth edition, the lectures have been wholly revised and almost entirely re-written, and no effort has been spared to bring them up to date in all essential points."

The *Literary World* says:—"'Spectrum Analysis' may be read not only by experts as a work of standard value, but also by that portion of the thoughtful public that cares for a lucid explanation of one of the most interesting, though, at the same time, one of the most intricate, branches of physical science."

SPECIALITIES.

Completely Disarticulated Skeleton of Young Jaguar, each individual Bone movable; natural position retained.

Complete Section of Cat, one side natural, the other disarticulated.

Fowl Skull fully disarticulated, the Bones movable in Groups; lettered after Parker.

Limulus Homarus, Palinurus, Cancer, and Scorpio, fully disarticulated; lettered after Huxley and Ray Lankester.

TWO GOLD MEDALS AWARDED LIVERPOOL EXHIBITION.

Specimens for Sale.

THE ZOOLOGIST:

A MONTHLY MAGAZINE OF NATURAL HISTORY.

Third Series. Edited by J. E. Harting, F.L.S., F.Z.S., Member of the British Ornithologists' Union; contains—

Original Articles by well-known naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds; occurrence of rare birds; distribution and migration of British freshwater fish; new or rare marine fish; local aquaria; British reptiles; British land and freshwater mollusca, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts.

JOHN VAN VOORST, 1, Paternoster Row.

On the 1st of every Month, price Sixpence.

THE ENTOMOLOGIST:

AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOGY.

Edited by John T. Carrington,
With the Assistance of

Frederick Bond, F.Z.S.	Richard South.
Edward A. Fitch, F.L.S.	J. Jenner Weir, F.L.S.

F. Buchanan White, M.D.

Contains Articles by well-known Entomologists on all Branches of the Science; on Insects injurious or beneficial to Farm or Garden; Notes on Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthly Lists of Duplicates and Desiderata.

Woodcut Illustrations and occasional Lithographed and Chromo-Lithographed Plates.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

MESSRS. MACMILLAN & CO.'S MANUALS FOR STUDENTS.

NATURAL PHILOSOPHY.

ELEMENTARY PRACTICAL PHYSICS, LESSONS IN. By Professor BALFOUR STEWART, F.R.S., and W. W. HALDANE GEE, B.Sc. Crown 8vo.

Part I.—GENERAL PHYSICAL PROCESSES. 6s.
Part II.—ELECTRICITY AND MAGNETISM. [*In the press.*
Part III.—OPTICS, HEAT, AND SOUND. [*In preparation.*

A SCHOOL COURSE OF PRACTICAL PHYSICS. By the same Authors. [*In preparation.*

ON LIGHT: Being the Burnett Lectures, delivered in Aberdeen in 1883–1884. By GEORGE GABRIEL STOKES, M.A., P.R.S., &c., Fellow of Pembroke College, and Lucasian Professor of Mathematics in the University of Cambridge. First Course. ON THE NATURE OF LIGHT.—Second Course. ON LIGHT AS A MEANS OF INVESTIGATION. Crown 8vo. 2s. 6d. each.

THIRD COURSE. ON THE BENEFICIAL EFFECTS OF LIGHT. [*In the press.*

MECHANICAL THEORY OF HEAT. By R. CLAUSIUS. Translated by WALTER R. BROWNE, M.A., late Fellow of Trinity College, Cambridge. Crown 8vo. 10s. 6d.

HEAT. By P. G. TAIT, M.A., Sec. R.S.E., formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh. Crown 8vo. 6s.

LIGHT; A COURSE OF EXPERIMENTAL OPTICS, CHIEFLY WITH THE LANTERN. By LEWIS WRIGHT. With 200 Engravings and Coloured Plates. Crown 8vo. 7s. 6d.

PHYSICAL ARITHMETIC. By ALEXANDER MACFARLANE, D.Sc., Examiner in Mathematics in the University of Edinburgh. Crown 8vo. 7s. 6d.

CHEMISTRY.

THE STUDY OF CHEMISTRY, AN INTRODUCTION TO. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

COMPOUNDS OF CARBON; or, Organic Chemistry, an Introduction to the Study of. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

BIOLOGY.

THE ELEMENTS OF EMBRYOLOGY. By MICHAEL FOSTER, M.A., M.D., LL.D., Sec. R.S., Professor of Physiology in the University of Cambridge, Fellow of Trinity College, Cambridge, and the late FRANCIS M. BALFOUR, M.A., LL.D., F.R.S., Fellow of Trinity College, Cambridge, and Professor of Animal Morphology in the University. Second Edition, revised. Edited by ADAM SEDGWICK, M.A., Fellow and Assistant Lecturer of Trinity College, Cambridge, and WALTER HEAPE, Demonstrator in the Morphological Laboratory of the University of Cambridge. With Illustrations. Crown 8vo. 10s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN ELEMENTARY BIOLOGY. By THOMAS HENRY HUXLEY, F.R.S., assisted by H. N. MARTIN, M.B., D.Sc. New Edition, revised. Crown 8vo. 6s.

A COURSE OF ELEMENTARY PRACTICAL PHYSIOLOGY. By Prof. MICHAEL FOSTER, M.D., Sec. R.S., &c., and J. N. LANGLEY, M.A., F.R.S., Fellow of Trinity College, Cambridge. Fifth Edition. Crown 8vo. 7s. 6d.

AN INTRODUCTION TO THE OSTEOLOGY OF THE MAMMALIA. By WILLIAM HENRY FLOWER, LL.D., F.R.S., Director of the Natural History Departments of the British Museum, late Hunterian Professor of Comparative Anatomy and Physiology in the Royal College of Surgeons of England. With numerous Illustrations. Third Edition. Revised with the assistance of HANS GADOW, Ph.D., M.A., Lecturer on the Advanced Morphology of Vertebrates and Strickland Curator in the University of Cambridge. Crown 8vo. 10s. 6d.

AN ATLAS OF PRACTICAL ELEMENTARY BIOLOGY. By G. B. HOWES, Assistant Professor of Zoology, Normal School of Science and Royal School of Mines. With a Preface by THOMAS HENRY HUXLEY, F.R.S. Royal 4to. 14s.

A COURSE OF INSTRUCTION IN ZOOTOMY (VERTEBRATA). By T. JEFFREY PARKER, B.Sc. London, Professor of Biology in the University of Otago, New Zealand. With Illustrations. Crown 8vo. 8s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, M.A., F.L.S., Professor of Botany in the University of Glasgow, and SYDNEY H. VINES, M.A., D.Sc., F.R.S., Fellow and Lecturer, Christ's College, Cambridge. With a Preface by W. T. THISELTON DYER, M.A., C.M.G., F.R.S., F.L.S., Director of the Royal Gardens, Kew.

Part I.—PHANEROGAMÆ—PTERIDOPHYTA. Crown 8vo. 6s.

STRUCTURAL BOTANY, OR ORGANOGRAPHY ON THE BASIS OF MORPHOLOGY. To which are added the Principles of Taxonomy and Phytography, and a Glossary of Botanical Terms. By Professor ASA GRAY, LL.D. 8vo. 10s. 6d.

THE STUDENT'S FLORA OF THE BRITISH ISLANDS. By Sir J. D. HOOKER, K.C.S.I., C.B., M.D., F.R.S., D.C.L. Third Edition, revised. Globe 8vo. 10s. 6d.

FIRST BOOK OF INDIAN BOTANY. By DANIEL OLIVER, F.R.S., &c., Professor of Botany in University College, London, &c. With Illustrations. Extra fcap. 8vo. 6s. 6d.

DOMESTIC BOTANY: An Exposition of the Structure and Classification of Plants, and their Uses for Food, Clothing, Medicine, and Manufacturing Purposes. By JOHN SMITH, A.L.S., &c. With Illustrations. New Issue. Crown 8vo. 12s. 6d.

EUROPEAN BUTTERFLIES, A HANDBOOK OF. By W. F. DE VISMES KANE, M.A., M.R.I.A., Member of the Entomological Society of London, &c. With Copper Plate Illustrations. Crown 8vo. 10s. 6d.

A LIST OF EUROPEAN RHOPALOCERA, WITH THEIR VARIETIES AND PRINCIPAL SYNONYMS. Reprinted from the *Handbook of European Butterflies*. Crown 8vo. 1s.

MEDICINE.

MICRO-ORGANISMS AND DISEASE. An Introduction into the Study of Specific Micro-Organisms. By E. KLEIN, M.D., F.R.S., Lecturer on General Anatomy and Physiology in the Medical School of St. Bartholomew's Hospital, London. With 121 Illustrations. Third Edition. Revised. Crown 8vo. 6s.

ANTHROPOLOGY.

ANTHROPOLOGY. An Introduction to the Study of Man and Civilisation. By E. B. TYLOR, D.C.L., F.R.S. With numerous Illustrations. Crown 8vo. 7s. 6d.

PHYSIOGRAPHY AND GEOLOGY.

PHYSIOGRAPHY. An Introduction to the Study of Nature. By THOMAS HENRY HUXLEY, F.R.S. With numerous Illustrations, and Coloured Plates. New and Cheaper Edition. Crown 8vo. 6s.

CLASS-BOOK OF GEOLOGY. By ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland, and Director of the Museum of Practical Geology, London, formerly Murchison Professor of Geology and Mineralogy in the University of Edinburgh, &c. With upwards of 200 New Illustrations. Crown 8vo. 10s. 6d.

AGRICULTURE.

AGRICULTURAL CHEMICAL ANALYSIS, A Handbook of. By PERCY FARADAY FRANKLAND, Ph.D., B.Sc., F.C.S., Associate of the Royal School of Mines, and Demonstrator of Practical and Agricultural Chemistry in the Normal School of Science and Royal School of Mines, South Kensington Museum. Founded upon *Leitfaden für die Agricultur Chemische Analyse*, von Dr. F. KROCKER. Crown 8vo. 7s. 6d.

POLITICAL ECONOMY.

A MANUAL OF POLITICAL ECONOMY. By Right Hon. HENRY FAWCETT, F.R.S. Sixth Edition, revised, with a chapter on "State Socialism and the Nationalisation of the Land," and an Index. Crown 8vo. 12s.

A BRIEF TEXT-BOOK OF POLITICAL ECONOMY. By FRANCIS A. WALKER, M.A., Ph.D., Author of "Money," "Money in its Relation to Trade," &c. Crown 8vo. 6s. 6d.

MORAL PHILOSOPHY AND LOGIC.

THE HISTORY OF ETHICS, OUTLINES OF, FOR ENGLISH READERS. By HENRY SIDGWICK, M.A., LL.D., Knightbridge Professor of Moral Philosophy in the University of Cambridge, Author of "The Methods of Ethics," "The Principles of Political Economy," &c. Crown 8vo. 3s. 6d.

THE ELEMENTS OF THE PSYCHOLOGY OF COGNITION. By the Rev. ROBERT JARDINE, B.D., D.Sc. (Edin.), Ex-Principal of the General Assembly's College, Calcutta. Second Edition, revised and improved. Crown 8vo. 6s. 6d.

STUDIES IN DEDUCTIVE LOGIC. By the late W. STANLEY JEVONS, LL.D., M.A., F.R.S. Second Edition. Crown 8vo. 6s.

ANCIENT GEOGRAPHY.

MANUAL OF ANCIENT GEOGRAPHY. Translated from the German of Dr. HEINRICH KIEPERT. Crown 8vo. 5s.

HISTORY.

SHORT HISTORY OF THE ENGLISH PEOPLE. By JOHN RICHARD GREEN, M.A., LL.D., late Honorary Fellow of Jesus College, Oxford. With Coloured Maps, Genealogical Tables, and Chronological Annals. Crown 8vo. 8s. 6d. 117th Thousand.

ANALYSIS OF ENGLISH HISTORY, based on Green's "Short History of the English People." By C. W. A. TAIT, M.A., Assistant Master, Clifton College. Crown 8vo. 3s. 6d.

GOLD MEDAL,
International Inventions Exhibition, 1885.

SEISMOGRAPHS.

These instruments form a complete apparatus for automatically registering e motion of the ground during earthquakes. They were originally designed y Prof. J. A. Ewing for the Seismological Observatory of the University f Tokio, where some of them have been in use since 1880. The forms now fered contain many improvements in detail, suggested by experience of rthquake measurement in Japan.

A fully-illustrated description and list of prices will be sent on application.

HE CAMBRIDGE SCIENTIFIC INSTRUMENT CO.,
Cambridge.

MOORE BROTHERS,
STEOLOGISTS, DISARTICULATORS, ETC.,

ENGINEERING.

CITY AND GUILDS OF LONDON INSTITUTE.

The Courses of Technical Instruction at the Central Institution, Exhibition Road, S.W., are open to persons desirous of studying CIVIL, MECHANICAL, ELECTRICAL, or CHEMICAL ENGINEERING.

The Courses comprise Lectures and Laboratory Practice, Instruction in the Drawing Office and in the Workshops. The Institution is furnished with Special Laboratories for Experiments in the Efficiency of the Steam-Engine, in the Testing of the Strength of Materials and the Power and Efficiency of Dynamos, and also for Experimental Work connected with different branches of Manufacturing Chemistry.

DYNAMO-ELECTRIC MACHINERY.

A Special Course of Practical Demonstrations in the Testing of the Power and Efficiency of Dynamos and Motors will be given by Prof. AYRTON, F.R.S., at the Central Institution, commencing on FRIDAY, February 4, 1887, at 5 p.m. Fee for the Course, £1 11s. 6d.

CHEMISTRY OF THE ALKALOIDS, &c.

Prof. ARMSTRONG, F.R.S., will commence a Course of about Twenty Lectures on JANUARY 17, 1887, at the Central Institution, Exhibition Road, S.W., on the Chemistry of Nitrogen and its Compounds, with Special Reference to Recent Investigations of the Alkaloids, Albumenoids, &c.

The Lectures will be given at 5 p.m. on MONDAYS and WEDNESDAYS. Fee for the Course, £1 1s.

For further particulars of any of the above Courses, apply at Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, *Director and Secretary.*

UNIVERSITY COLLEGE, LIVERPOOL.

SHERIDAN MUSPRATT CHEMICAL SCHOLARSHIP,

Of the value of £50 per Annum, tenable for Two Years.

The Examination for this Scholarship will commence on DECEMBER 9, the subjects of Examination being —

The Principles of Chemistry
Chemistry of the Metals and Non-Metals
Elements of Organic Chemistry.
Qualitative Analysis and General Laboratory Work.
Simple Quantitative Analysis.

The Examination in these subjects will extend over three days, one at least of which will be devoted to practical work in the Laboratory. Candidates who have not taken a University Degree will further be required to satisfy the Examiners in :—

(1) Physics, especially Heat and Electricity.
(2) Mathematics; especially Algebra up to Binomial Theorem and Logarithms.

The Examination is open to all, but preference will be given to Candidates under twenty-three years of age, provided that they come up to the requisite standard.

Candidates should send their names on or before December 6 to the REGISTRAR.

LECTURE.—On TUESDAY, December 7,

at WILLIS'S ROOMS, King Street, St. James's, by ARTHUR A. CUTHBERT. Subject: "The True Fundamental Principles of Science: illustrated by *Astronomy* (especially the latest Discoveries and Demonstrations thereof) as it stands related to Science in general, and to *Human Life and its Evolution.*" "Sermons in stones, and Truth in everything." Lecture to commence at 8 p.m. Reserved Seats, 5s and 2s. 6d. Unreserved Seats, 1s. Tickets can be had at the Rooms and the usual Libraries.

JOHN HAMPDEN or ISAAC NEWTON?

—Is it lack of brains or lack of moral courage that delays the verdict, or is the manhood of England a thing of the past? Read *The Earth*, Fortnightly, One Penny.—29, Paternoster Row.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to
THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers some unrecognised Flagellate Monads, with sketch and description. He also sent out Argulus foliaceus, Acineta grandis, Stephanoceros Eichornii, Cephalosiphon limnias, Conochilus volvox, Brachionus urceolaris, Eurycercus lamellatus, Sida crystallina, Difflugia, Desmids, Volvox globator, also Hydra, Amoeba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms, T. B. supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s. or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

S. LOUIS'S SERIES OF UNMOUNTED OBJECTS FOR THE MICROSCOPE.

11 Series of Diatoms (12 tubes in each), at 3s. each series.
46 ,, Various Objects (12 to 36 in each) at 2s. ditto.

S. LOUIS'S SERIES OF *MOUNTED* OBJECTS.

43 Series, twelve (3 by 1) slides in each, at 5s each Series. 10th Series of selected Diatoms ready

36 Pages, New Detailed List, post free for One Stamp.

SOLE AGENT: WM. WEST, 15, Horton Lane, Bradford.

MORPHOLOGY OF THE CRUSTACEÆ.

The following interesting and rarely-observed objects, stained and mounted in balsam without pressure, 1s. 6d. each :—

The Curious Zoëa of "Porcellana platycheles."
Do. of Plated Lobster, "Galathea."
Do. of Great Edible Crab, "Cancer pagurus."
Do of Shore Crab, "Carcinus mænas."
Megalopa Stage of ditto.
Young of Hermit Crab, "Pagurus bernhardus."
Zoëa of Prawn, and Mysis Stage of ditto.

SINEL & CO., JERSEY.

N.B.—Communications, &c., should be sent to the Editors at the above address.

NORTH BRITISH AGRICULTURIST,

the chief Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3*d.* By post 3½*d.* Annual Subscription, payable in advance, 14*s.*

Offices—377, High Street, Edinburgh; and 245, Queen Victoria Stre London, E.C. Money Orders payable to C. and R. ANDERSON.

HOLLOWAY'S OINTMENT **AN INFALLIBLE REMEDY**

For BAD LEGS, BAD BREASTS, OLD WOUNDS, SORES and ULCERS. If effectually rubbed on the Neck and Chest, it cures SORE THROATS, BRONCHITIS, COUGHS and COLDS; and for GOUT, RHEUMATISM, and all Skin Diseases it is unequalled.

MESSRS. MACMILLAN AND CO.'S NEW BOOKS.

A TEXT-BOOK OF

PATHOLOGICAL ANATOMY AND PATHOGENESIS.

By ERNST ZIEGLER, Professor of Pathological Anatomy in the University of Tubingen.

Translated and Edited for English Students by DONALD MACALISTER, M.A., M.D., B.Sc., F.R.C.P., Fellow and Medical Lecturer of St. John's College, Cambridge, Physician to Addenbrooke's Hospital, and University Lecturer in Medicine. With numerous Illustrations. PART II.—SPECIAL PATHOLOGICAL ANATOMY. Sections IX.-XII. 8vo. 12*s.* 6*d.* [*Next week.*

Part I.—General Pathological Anatomy. 12*s* 6*d.* Part II.—Special Pathological Anatomy. Sections I.-VIII. 12*s.* 6*d.* Sections IX.-XII. 12*s.* 6*d.*

A TREATISE ON CHEMISTRY.

By Sir H. E. ROSCOE, F.R.S., and C. SCHORLEMMER, F.R.S.,

Professors of Chemistry in the Victoria University, Owens College, Manchester. With Illustrations. VOLUME III.—ORGANIC CHEMISTRY. Part III. Demy 8vo. 18*s.* [*Next Week.*

Volumes I. and II.—INORGANIC CHEMISTRY Vol. I.—The Non-Metallic Elements With a Portrait of DALTON, Engraved by C. H. JEENS. 21*s.* Vol. II. Part I.—Metals. 18*s.* Vol. II. Part II.—Metals. 18*s.* Vol. III. Three Parts.—ORGANIC CHEMISTRY. Parts I. and II. 21*s.* each. Part III. 18*s.*

MESSRS. MACMILLAN AND CO.'S

TEXT-BOOKS FOR STUDENTS.

NATURAL PHILOSOPHY.

Applied Mechanics: an Elementary General Introduction to the Theory of Structures and Machines By JAMES H. COTTERILL, F.R.S., Associate Member of the Council of the Institution of Naval Architects, Associate Member of the Institution of Civil Engineers, Professor of Applied Mechanics in the Royal Naval College, Greenwich Medium 8vo. 18s.

A Text-Book of the Principles of Physics. By ALFRED DANIELL, M A, LL B, D.Sc., F R.S E, late Lecturer on Physics in the School of Medicine, Edinburgh. With Illustrations. Second Edition. Revised and Enlarged. Medium 8vo. 21s.

The Kinematics of Machinery. Outlines of a Theory of Machines. By Professor F. REULEAUX. Translated and Edited by Professor A B. W. KENNEDY, C.E. With 450 Illustrations Medium 8vo. 21s.

Spectrum Analysis. Lectures delivered in 1868 before the Society of Apothecaries of London. By Sir HENRY E. ROSCOE, LL D, F.R.S, Professor of Chemistry in the Owens College, Victoria University, Manchester. Fourth Edition, revised and considerably enlarged by the Author and by ARTHUR SCHUSTER, F.R.S., Ph D, Professor of Applied Mathematics in the Owens College, Victoria University With Appendices, numerous Illustrations, and Plates. Medium 8vo. 21s.

Electrostatics and Magnetism. Reprints of Papers on By Sir WILLIAM THOMSON, D C L., LL D, F R.S., F R S.E, Fellow of St. Peter's College, Cambridge, and Professor of Natural Philosophy in the University of Glasgow. Second Edition. Medium 8vo. 18s.

ASTRONOMY.

Popular Astronomy. By S. NEWCOMB, LL.D., Professor U.S Naval Observatory. With 112 Illustrations and 5 Maps of the Stars. Second Edition, revised. 8vo. 18s.

CHEMISTRY.

Inorganic and Organic Chemistry. A Complete Treatise on Inorganic and Organic Chemistry. By Sir HENRY E. ROSCOE, F.R.S., and Professor C. SCHORLEMMER, F.R S. With numerous Illustrations. Medium 8vo

Vols. I. and II.—INORGANIC CHEMISTRY.

Vol. I.—The Non-Metallic Elements. 21s. Vol. II. Part I.—Metals. 18s Vol II. Part II.—Metals 18s

Vol III.—ORGANIC CHEMISTRY. Three Parts.

The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. With numerous Illustrations. Medium 8vo. Parts I and II., 21s each. Part III, 18s.

Elements of Chemical Physics. By JOSIAH P. COOKE, Junr, Erving Professor of Chemistry and Mineralogy in Harvard University. Fourth Edition. Royal 8vo. 21s

A Manual of the Chemistry of the Carbon COMPOUNDS, OR ORGANIC CHEMISTRY. By C SCHORLEMMER, F R.S., Professor of Chemistry in the Victoria University, the Owens College, Manchester With Illustrations. 8vo 14s.

The Elements of Thermal Chemistry. By M. M. PATTISON MUIR, M A., F R.S.E, Fellow and Prælector of Chemistry in Gonville and Caius College, Cambridge; Assisted by DAVID MUIR WILSON. 8vo 12s. 6d.

BIOLOGY.

A Text-Book of Physiology. By MICHAEL FOSTER, M.D., Sec. R S, Professor of Physiology in the University of Cambridge With Illustrations. Fourth Edition, revised. 8vo 21s.

Elements of the Comparative Anatomy of VERTEBRATES Adapted from the German of ROBERT WIEDERSHEIM, Professor of Anatomy, and Director of the Institute of Human and Comparative Anatomy in the University of Frieburg-in-Baden. By W NEWTON PARKER, Professor of Biology in the University College of South Wales and Monmouthshire. With Additions by the Author and Translator. With Two Hundred and Seventy Woodcuts Medium 8vo 12s. 6d.

A Treatise on Comparative Embryology. By F. M. BALFOUR, M A., F.R S., Fellow and Lecturer of Trinity College, Cambridge. With Illustrations. Second Edition, reprinted without alteration from the First Edition. In 2 vols 8vo. Vol. I. 18s. Vol. II 21s.

Elements of Comparative Anatomy. By Professor CARL GEGENBAUR. A Translation by F. JEFFREY BELL, B A Revised with Preface by Professor E. RAY LANKESTER, F R S. With numerous Illustrations. 8vo. 21s.

BIOLOGY—*continued.*

A Text-Book of the Physiological Chemistry OF THE ANIMAL BODY. Including an Account of the Chemical Changes occurring in Disease. By A. GAMGEE, M.D., F R.S., Professor of Physiology in the Victoria University, the Owens College, Manchester. 2 Vols. 8vo. With Illustrations. Vol. I 18s.

[*Vol II in the press.*

The Fertilisation of Flowers. By Professor HERMANN MÜLLER. Translated and Edited by D'ARCY W. THOMPSON, B.A., Professor of Biology in University College, Dundee. With a Preface by CHARLES DARWIN, F R.S. With numerous Illustrations. Medium 8vo 21s.

A Dictionary of Economic Plants. Their History, Products, and Uses. By JOHN SMITH, A.L.S., &c. 8vo. 14s.

MEDICINE.

A Text-Book of Pharmacology, TheraPEUTICS, AND MATERIA MEDICA. By T. LAUDER BRUNTON, M.D, D Sc., F.R C.P, F R S., Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital, Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London, late Examiner in the University of Edinburgh. Adapted to the United States Pharmacopœia, by FRANCIS H WILLIAMS, M.D., Boston, Mass. Second Edition Adapted to the New British Pharmacopœia, 1885. Medium 8vo. 21s.

Tables of Materia Medica: a Companion to the Materia Medica Museum. By the same Author. With Illustrations. New Edition Enlarged. 8vo. 10s. 6d.

Text-Book of Pathological Anatomy and PATHOGENESIS. By Professor ERNST ZIEGLER of Tubingen. Translated and Edited for English Students by DONALD MACALISTER, M A, M D, B Sc, F R C.P, Fellow and Medical Lecturer of St. John's College, Cambridge, Physician to Addenbrooke's Hospital, and Teacher of Medicine in the University. With numerous Illustrations. Medium 8vo.

Part I.—GENERAL PATHOLOGICAL ANATOMY. 12s 6d.

Part II.—SPECIAL PATHOLOGICAL ANATOMY. Sections I.—VIII. 12s. 6d. Sections IX.—XII. 12s. 6d.

GEOLOGY.

Text-Book of Geology. By ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland, and Director of the Museum of Practical Geology, London, formerly Murchison Professor of Geology and Mineralogy in the University of Edinburgh, &c. With numerous Illustrations. Second Edition. Fifth Thousand Revised and Enlarged. 8vo. 28s.

A Treatise on Ore Deposits. By J. ARTHUR PHILLIPS, F.R S., V.P.G S., F.C S, M Inst C E., Ancien Elève de l'Ecole des Mines, Paris, Author of "A Manual of Metallurgy," "The Mining and Metallurgy of Gold and Silver," &c. With numerous Illustrations. 8vo 25s.

POLITICAL ECONOMY.

The Principles of Political Economy. By Professor HENRY SIDGWICK, M A., LL D, Knightbridge Professor of Moral Philosophy in the University of Cambridge, &c., Author of "The Methods of Ethics." 8vo. 16s.

Political Economy. By FRANCIS [illegible] WALKER, M A, Ph.D., Author of "Money," "Money in its Relation to Trade," &c. 8vo. 10s. 6d.

MENTAL AND MORAL PHILOSOPHY.

The Methods of Ethics. By Professor HENRY SIDGWICK, M A., LL D. Cambridge, &c. Third Edition 8vo. 14s. A Supplement to the Second Edition, containing all the important Additions and Alterations in the Third Edition. Demy 8vo. 6s.

Critique of Pure Reason. By IMMANUEL KANT. In commemoration of the Centenary of its first Publication Translated into English by F MAX MÜLLER. With an Historical Introduction by LUDWIG NOIRÉ. Two vols. Demy 8vo 16s. each.

Vol. I. HISTORICAL INTRODUCTION, by LUDWIG NOIRÉ; &c

Vol II. CRITIQUE of PURE REASON, translated by F. MAX MÜLLER.

For the convenience of students these volumes are now sold separately.

Of Prof Max Muller's translation of the "Critique of Pure Reason," the *Times* says:—"Through this translation Kant's work has for the first time become international—the common property of the whole world."

⁂ *Other Volumes to follow.*

MACMILLAN & CO., LONDON.

WATSON & SONS' NEW HISTOLOGICAL MICROSCOPE.

FREE ON APPLICATION.

ILLUSTRATED CATALOGUE
OF
MICROSCOPES
AND
APPARATUS.

Classified List of 40,000 First-class Microscopic Objects.

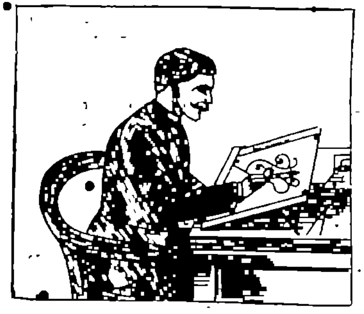
A thoroughly first-rate Microscope at an extremely moderate price. It is mounted on an exceedingly firm brass foot, has sliding body for coarse adjustment, draw-tube, plane and concave mirrors, tube fitting of universal size for under-stage apparatus, with special arrangement for oblique illumination, set of diaphragms, with pin-hole stop, and is fitted with WATSON & SON'S improved form of fine adjustment, as supplied to their best instruments, which is perfectly free from all lateral motion, even when working with the highest powers, and permits of the greatest possible delicacy of adjustment. The entire instrument is finished in the very best manner, and is unequalled in value at the price.

Microscope as illustrated, with "C" eye-piece, ¼ and 1 inch first-class English objectives, giving a range of amplification from 75 to 700 diameters, in mahogany cabinet, price

£4 15s. 0d.

W. WATSON & SONS, Opticians to H.M. Government,
313, HIGH HOLBORN, LONDON, W.C. ESTABLISHED 1837.

THE "GEBHARDT" PATENT DRAWING-BOARD.



The introduction of our Patent Supports, for Drawing or other Artists' Boards, provides for a long-felt want. Most Students have experienced great difficulty, at some time or other, in supporting their work at the proper angle, and even when this had been accomplished to their apparent satisfaction, it has been speedily followed by failure, through the supports suddenly and unexpectedly giving way.

The arrangement is of **SIMPLE CONSTRUCTION** and **NOT LIABLE TO GET OUT OF ORDER.** It is **EASY TO ALTER TO THE REQUIRED ELEVATION,** and when closed there are no projections, but a perfectly flat surface, making it as compact and portable as those Boards which are without the Attachment

By placing the Board on the reverse side, with the Supports projecting, it will be found the right elevation for painting, and thus serve the purpose of an Easel.

The Boards are made of the best Dry Timber, and the Supports of the best Malleable Iron.

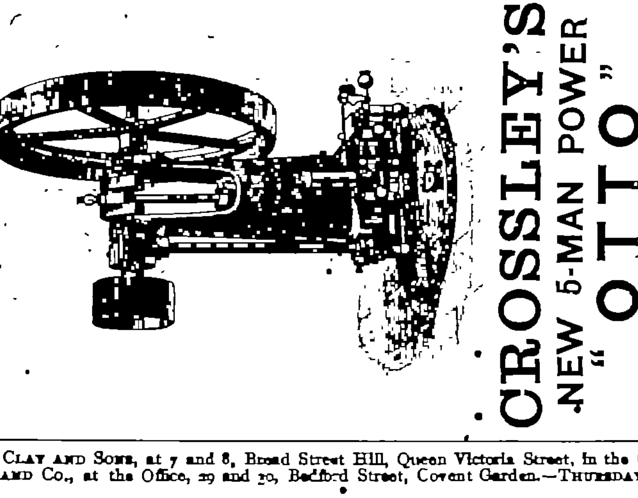
This often happens when using the old kinds.

THEY SHOULD FIND THEIR WAY INTO EVERY SCHOOL, OFFICE, OR ARTISTS' STUDIO.

No. 100, Deal Clamped: Size, 16 × 12 inches, 2s. 3d.; 22 × 17 inches, 3s. 3d., 40 × 27 inches, 8s 3d

HARGER BROTHERS, SETTLE, YORKSHIRE.

THE "OTTO" GAS-ENGINE. OVER 20,000 SOLD.



CROSSLEY'S NEW 5-MAN POWER "OTTO"

GIVES OFF 1 H.P. ON THE BRAKE.

Very suitable for driving amateurs' workshop, pumping water to house, driving laundry machinery, chaff-cutting, &c.

Can be supplied combined with pumps or with dynamo for electric lighting (the dynamo or pump being disconnected when engine is required for other purposes).

CROSSLEY BROS., Limited, MANCHESTER.

CHRISTMAS LECTURES.

ROYAL INSTITUTION OF GREAT BRITAIN,

ALBEMARLE STREET, PICCADILLY, W.

Prof. DEWAR, M.A., F.R.S., will deliver a Course of Six Lectures (adapted to a Juvenile Auditory) on "The Chemistry of Light and Photography" (with Experimental Illustrations), commencing on TUESDAY, December 28, 1886, at 3 o'clock; to be continued on December 30, and January 1, 4, 6, 8, 1887. Subscription (for Non-Members) to this Course, One Guinea (Children under sixteen, Half-a-Guinea); to all the Courses in the Season, Two Guineas. Tickets may now be obtained at the Institution.

CHEMISTRY OF THE ALKALOIDS, ETC.

CITY AND GUILDS OF LONDON INSTITUTE.

Prof. ARMSTRONG, F.R.S., will commence a Course of about Twenty Lectures on January 27, 1887, at the CENTRAL INSTITUTION, Exhibition Road, S.W., on the CHEMISTRY of NITROGEN and its COMPOUNDS, with Special Reference to Recent Investigations of the ALKALOIDS, ALBUMENOIDS, &c. The Lectures will be given at 5 p.m. on MONDAYS and WEDNESDAYS. Fee for the Course, £1 1s. For further particulars apply at the Central Institution, Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary

The NEW ATHENÆUM CLUB (Scientific, Literary, and Social) has VACANCIES for a limited number of ADDITIONAL MEMBERS without Entrance Fee.—Particulars, with List of Vice-Presidents and Committee, will be forwarded on application to the SECRETARY, 26, Suffolk Street, Pall Mall.

BOOKS (Secondhand), Miscellaneous, Remainders, &c.—C. HERBERT, English and Foreign Bookseller, 319, Goswell Road, London, E.C. Catalogue free on receipt of two stamps. Libraries, Old Books, and Parchments purchased.

CHEMICAL ENGINEERING.

CITY AND GUILDS OF LONDON INSTITUTE.

Course of Technical Instruction for Chemists, Manufacturers, and others, including Practice in Chemical Engineering and Physical Laboratories, under the direction of Prof. ARMSTRONG, Ph.D., F.R.S.

For particulars apply at the CENTRAL INSTITUTION, Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

TWO ENTRANCE SCIENCE SCHOLARSHIPS of 125 Guineas and £60 respectively, open to all First-Year Students will be offered for Competition in OCTOBER 1887.

Special Classes are held throughout the Year for the "PRELIMINARY SCIENTIFIC" and "INTERMEDIATE M.B." Examinations of the University of London, and may be joined at any time.

Entries may be made to Lectures or to Hospital Practice, and special arrangements are made for Students entering in their Second or subsequent Years; also for Dental Students, and for Qualified Practitioners.

Prospectuses and all particulars may be obtained from the Medical Secretary, Mr. GEORGE RENDLE. W. M. ORD, Dean.

JOHN HAMPDEN or ISAAC NEWTON?—Is it lack of brains or lack of moral courage that delays the verdict, or is the manhood of England a thing of the past? Read *The Earth*, Fortnightly, One Penny.—29, Paternoster Row.

W. P. COLLINS, SCIENCE BOOKSELLER—Secondhand and New. Catalogues and Monthly Lists free for Two Stamps. Libraries and Parcels of Books purchased or taken in exchange.—157, Great Portland Street, Oxford Street, London, W.

ZEISS MICROSCOPE STANDS in STOCK in handsome Nickel mounted Cabinets. Verified Objectives, ordinary and the new Apochromatic. List, W. HUME, Optician, Lothian Street, Edinburgh.

MOORE BROTHERS will be pleased to show their collection of Skulls, Skeletons, Crustacea, and Models to any Biologists or others interested, who may be visiting Liverpool, if they will kindly notify date and time of intended visit to the Laboratory, 14, *Gardner Road*, Tue Brook.

MOORE BROTHERS.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers Stephanoceros Eichornii, with drawing and description. He also sent out Floscularia campanulata, Floscularia cornuta, Cephalosiphon limnias, Melicerta ringens, Brachionus urceolaris, Eurycercus lamellatus, Sida crystallina, Argulus foliaceus, Difflugia, Desmids, Volvox globator; also Hydra, Amœba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory Work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s., *or Twelve Tubes for* 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

S. LOUIS'S SERIES OF UNMOUNTED OBJECTS FOR THE MICROSCOPE.

11 Series of Diatoms (12 tubes in each), at 3s. each Series.
46 " Various Objects (12 to 36 in each) at 2s. ditto.

S. LOUIS'S SERIES OF *MOUNTED* OBJECTS.

43 Series, twelve (3 by 1) slides in each, at 5s. each Series. 10th Series of selected Diatoms ready.

36 Pages, New Detailed List, post free for One Stamp.

SOLE AGENT: WM. WEST, 15, Horton Lane, Bradford.

MORPHOLOGY OF THE CRUSTACEÆ.

The following interesting and rarely-observed objects, stained and mounted in balsam without pressure, 1s. 8d. each:—

The Curious Zoëa of "Porcellana platycheles."
Do. of Plated Lobster, "Galathea."
Do. of Great Edible Crab, "Cancer pagurus."
Do. of Shore Crab, "Carcinus mœnas."
Megalopa Stage of ditto.
Young of Hermit Crab, "Pagurus bernhardus."
Zoea of Prawn, and Mysis Stage of ditto.

SINEL & CO., JERSEY.

Complete Catalogue of Specimens for Museum, Laboratory, and Microscope, Two Stamps. 1467

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1s. per bottle, with full instructions for use, from most Opticians. Post free for 1s. 3d. from

EDWARD WARD, 249, Oxford Street, Manchester.

MINERALOGY AND GEOLOGY.

CHOICE SPECIMENS FOR MUSEUMS AND PRIVATE COLLECTORS: BERYLS, TOPAZES, RUTILES ON MATRIX, CELESTINE, OPALS, &c., &c.

RARE MINERALS FOR SCIENTIFIC RESEARCH; COLLECTIONS FOR STUDENTS AND PROSPECTORS.

VERY FINE POLISHED SECTIONS OF AMMONITES AND NAUTILI.

FLOWERS AND FLOWER-LORE. By Rev. HILDERIC FRIEND, F.L.S. Second Edition. Demy 8vo, Illustrated. 7*s*. 6*d*.

"A full study of a very fascinating subject. . . . It forms a perfect treasury of curious and out-of-the-way flower 'learning.' . . . Altogether the work is an important and exhaustive one, and occupies a distinct place of its own."—*Times*.

THE WANDERINGS of PLANTS AND ANIMALS. By Prof. VICTOR HEHN. Edited by J. STEPHEN STALLYBRASS. Demy 8vo, cloth, 16*s*.

"No more interesting work can be imagined. . . . A profusion of learning is spent on every chapter, at every turn some odd piece of classical lore turns up. Every student of Nature, as well as every scholar, will be grateful to Mr. Stallybrass for his book. He gives them in their own tongue a great body of erudition and a collection of striking facts. The index is excellent, and particular attention should be drawn to the notes, which are most valuable, and run to one hundred pages."—*Academy* (Rev. M. G. Watkins)

THE DYNAMO: How Made, and How USED. By S. R. BOTTONE. Numerous Cuts. Crown 8vo, cloth, 2*s* 6*d*.

"Exceedingly plain, clear instructions for the manufacture of small dynamos."—*Journal of Science*.

From the COLLECTOR'S SERIES:

Crown 8vo, cloth boards, 1*s* each.

ENGLISH COINS AND TOKENS. By LLEW. JEWITT, F.S.A. With a Chapter on Greek Coins, by BARCLAY V. HEAD (Brit. Mus.).

"This little work is eminently trustworthy and valuable."—*Notes and Queries*.

"A capital volume which no collector should be without."—*Glasgow Herald*.

CRUSTACEANS AND SPIDERS. By F. A. A. SKUSER. [*Just published*.

With 100 Woodcuts and 50 Diagrams, 6*s*.

LIFE-HISTORIES of PLANTS. With an Introductory Section on the Comparative Study of Plants and Animals. By Prof. D. McALPINE

8vo, limp cloth, with Coloured Flowered Chart of Europe, pp. xlviii.–366 2*s*. 6*d*.

THE NATURALIST'S DIARY: A DAY-BOOK OF METEOROLOGY, PHENOLOGY, AND RURAL BIOLOGY. Arranged and Edited by CHAS. ROBERTS, F.R.C.S., L.R.C.P., &c.

"A delightful device. . . Will make every man his own White of Selborne."—*Saturday Review*.

"The 'Naturalist's Diary' does infinite credit to the industry and zeal of Mr. Roberts, and cannot but prove a boon to all lovers of Nature."—*Academy*.

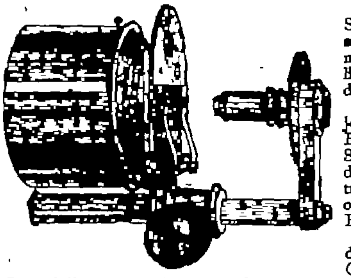
Shortly will be published.

TEXT-BOOK OF PRACTICAL BOTANY: a Manual for Students. Edited from the work of Prof. W. STRASBURGER, by Prof. W. HILLHOUSE, M.A., of the Mason College, Birmingham. Illustrated by a large number of New Woodcuts 8vo

SWAN SONNENSCHEIN, LOWREY, & CO., PATERNOSTER SQUARE.

NEW MICROSCOPIC ATTACHMENT FOR LANTERNS

(NEWTON'S PATENT).



(Suitable for any Lantern)

Shows ordinary 3 × 1 Microscopic Objects 8 feet in diameter with Lime-light, brilliantly illuminated, and sharply defined to the edge.

Any ordinary Microscope Objectives may be used with it. Every hair, on *Flea*, or other Small Insect, shows clearly and distinctly on Screen. Will show transverse striations in Trachea of *Dytiscus*, spiral formation of Blowfly's Tongue, &c. &c.

Complete with Sub-stage Condenser, and Double Achromatic Objective, Rotating Diaphragm, Rack Adjustment for Focusing, &c. Best Workmanship throughout. 94s.

Can be seen at work by intending Purchasers at 3, Fleet Street

For Particulars of Newton's Patent Magic Lanterns, Scientific and other Slides, Polariscopes, Microscopes, and Micro-Polariscopes for Screen Projection, Optical and Electric Lanterns, see Catalogue of Projection Apparatus, Four Stamps SILVER MEDAL INVENTIONS EXHIBITION, 1885.

NEWTON & CO., 3, Fleet Street, London, E.C.,

Opticians to the Queen and Government, Makers of every Description of Scientific and Physical Apparatus for Colleges, &c. Special Apparatus for Polariscopy, Spectroscopy, &c., for Screen Projection

Full Illustrated Catalogues 6 Stamps.

Diary of Societies

LONDON

THURSDAY, DECEMBER 9.

ROYAL SOCIETY, at 4.30.—Note to a Paper on the Geometrical Construction of the Cell of the Honey-Bee: Prof. H. Hennessy, F.R.S.—A New Method for the Quantitative Estimation of the Micro-organisms present in the Atmosphere: Dr P. F. Frankland.—Further Experiments on the Distribution of Micro-organisms in Air (by Hesse's method): Dr. P. F. Frankland and T. G. Hart.—On the Intra-ovarian Egg of some Osseous Fishes: Dr. R. Scharff.—Note on a New Form of Direct-Vision Spectroscope: Prof. Liveing, F.R.S., and Prof. Dewar, F.R.S.

MATHEMATICAL SOCIETY, at 8.—Circular Notes: R. Tucker.—On the Linear Partial Differential Equations satisfied by Pure Ternary Reciprocants: E. B. Elliott.—The Problem of Duration of Play: Capt. Macmahon.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS, at 8.—Annual General Meeting.

FRIDAY, DECEMBER 10.

ROYAL ASTRONOMICAL SOCIETY, at 8.

SATURDAY, DECEMBER 11.

PHYSICAL SOCIETY, at 3.—On the Influence of Change of Condition from the Liquid to the Solid State on Vapour-Pressure; and On the Nature of Liquids as shown by a Study of the Thermal Properties of Stable and Dissociable Bodies: Prof. W. Ramsay and Dr. Sidney Young.—On Cauchy's Theory of Reflection and Refraction: James Walker.

SUNDAY, DECEMBER 12.

SUNDAY LECTURE SOCIETY, at 4.—The Skeleton and its History (with Oxy-hydrogen Lantern Illustrations): Dr. Andrew Wilson, F.R.S.E.

MONDAY, DECEMBER 13.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Journey of the Expedition under Colonel Woodthorpe, R.E., from Upper Assam to the Irawadi, and return over the Patkoi Range: Major C. R. Macgregor (Bengal Staff Corps).

TUESDAY, DECEMBER 14.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—Papuans and Polynesians: Rev George Brown.—Notes on Songs and Song-Makers of some Australian Tribes: A. W. Howitt, F.G.S.—Music of the Australian Aborigines, G. W. Torrance, M.A., Mus.D.—On the Aborigines of Western Australia: R. H. Bland.

INSTITUTION OF CIVIL ENGINEERS, at 8.

WEDNESDAY, DECEMBER 15.

ROYAL METEOROLOGICAL SOCIETY, at 7.—On the Proceedings of the International Congress of Hydrology and Climatology at Biarritz: G. J. Symons, F.R.S.—Report on the Phenological Observations for 1886: Rev. T. A. Preston, M.A.—A Criticism of certain Points of Prof. Langley's Researches on Solar Heat: Prof. S. A. Hill, B.Sc.—Account of the Hurricane of March 4, 1886, over the Fiji Islands: R. L. Holmes.—Results of Meteorological Observations made at the Military Cemetery, Scutari, Constantinople, 1866-85: W. H. Lyne.

GEOLOGICAL SOCIETY, at 8.—Notes on Nummulites elegans, Sow., and other English Nummulites: Prof. T. Rupert Jones, F.R.S.—On the Dentition and Affinities of the Selachian Genus Ptychodus, Agassiz: A. Smith Woodward.—On a Molar of a Pliocene Equus from India: R. Lydekker, B.A.

THURSDAY, DECEMBER 16.

ROYAL SOCIETY, at 4.30.

LINNEAN SOCIETY, at 8.—On Apospory and Allied Phenomena: Prof. F. O. Bower.—Experiments on the Sense of Smell in Dogs: Dr. G. J. Romanes.—On a New Instance of Apospory in Polytrichum angulare: C. T. Druery.

CHEMICAL SOCIETY, at 8.—Researches on the Constitution of "Azo- and Diazo-derivatives." I. Diazoamido-compounds: R. Meldola, F.R.S., and F. W. Streatfield.—The Influence of Silicon on the Properties of Iron and Steel: Thomas Turner.

BEST BLACK INK KNOWN:
DRAPER'S INK (DICHROIC).
DIFFERING FROM ANYTHING ELSE EVER PRODUCED.

Writing becomes a pleasure when this Ink is used. It has been adopted by the principal Banks, Public Offices, and Railway Companies throughout Ireland.

It writes almost instantly full Black.
Does not corrode Steel Pens.
Is cleanly to use, and not liable to Blot.
Flows easily from the Pen
Blotting-paper may be applied at the moment of writing.

Can be obtained in London, through Messrs. BARCLAY & SONS, Farringdon Street; W. EDWARDS, Old Change; F. NEWBERY & SONS, Newgate Street; and to be had of all Stationers.

BEWLEY & DRAPER (Limited), Dublin.

London: WEST, NEWMAN, & CO., 54, Hatton Garden, E.C.

THE ZOOLOGIST:
A MONTHLY MAGAZINE OF NATURAL HISTORY.

Third Series. Edited by J. E. Harting, F.L.S., F.Z.S., Member of the British Ornithologists' Union; contains—

Original Articles by well-known naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds; occurrence of rare birds; distribution and migration of British fresh-water fish; new or rare marine fish; local aquaria; British reptiles; British land and fresh-water mollusca, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts.

JOHN VAN VOORST, 1, Paternoster Row.

On the 1st of every Month, price Sixpence.

THE ENTOMOLOGIST:
AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOGY.

Edited by John T. Carrington,

With the Assistance of

Frederick Bond, F.Z.S. | Richard South.
Edward A. Fitch, F.L.S. | J. Jenner Weir, F.L.S.
F. Buchanan White, M.D.

Contains Articles by well-known Entomologists on all Branches of the Science; on Insects injurious or beneficial to Farm or Garden; Notes on Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthly Lists of Duplicates and Desiderata.

Woodcut Illustrations and occasional Lithographed and Chromo-Lithographed Plates.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court

MESSRS. MACMILLAN AND CO.'S NEW BOOKS.

A TEXT-BOOK OF
PATHOLOGICAL ANATOMY AND PATHOGENESIS.

By ERNST ZIEGLER, Professor of Pathological Anatomy in the University of Tübingen. Translated and Edited for English Students by Donald Macalister, M.A., M.D., B.Sc., F.R.C.P., Fellow and Medical Lecturer of St. John's College, Cambridge, Physician to Addenbrooke's Hospital, and University Lecturer in Medicine. With numerous Illustrations. Part II.—SPECIAL PATHOLOGICAL ANATOMY. Sections IX.-XII. 8vo. 12s. 6d.

Part I.—General Pathological Anatomy. 12s. 6d. Part II.—Special Pathological Anatomy. Sections I.-VIII. 12s. 6d. Sections IX.-XII. 12s. 6d.

A TREATISE ON CHEMISTRY.

By Sir H. E. ROSCOE, F.R.S., and C. SCHORLEMMER, F.R.S., Professors of Chemistry in the Victoria University, Owens College, Manchester. With Illustrations. Volume III.—ORGANIC CHEMISTRY. Part III. Demy 8vo. 18s.

Volumes I. and II.—Inorganic Chemistry. Vol. I.—The Non-Metallic Elements. With a Portrait of Dalton, Engraved by C. H. Jeens. 21s. Vol. II. Part I.—Metals. 18s. Vol. II. Part II.—Metals. 18s. Vol. III. Three Parts.—Organic Chemistry. Parts I. and II. 21s. each. Part III. 18s.

MACMILLAN & CO., LONDON.

FOURTH EDITION, Revised and Considerably Enlarged.

SPECTRUM ANALYSIS.

SIX LECTURES DELIVERED IN 1868 BEFORE THE SOCIETY OF APOTHECARIES OF LONDON.

BY

SIR HENRY E. ROSCOE, LL.D. F.R.S.,

Professor of Chemistry in the Victoria University, Owens College, Manchester.

FOURTH EDITION, REVISED AND CONSIDERABLY ENLARGED BY THE AUTHOR AND

ARTHUR SCHUSTER, Ph.D., F.R.S.,

Professor of Applied Mathematics in Owens College, Victoria University.

With Appendices and numerous Illustrations and Plates. Medium 8vo. 21s.

MACMILLAN & CO., LONDON.

MESSRS. MACMILLAN AND CO.'S
TEXT-BOOKS FOR STUDENTS.

NATURAL PHILOSOPHY.

Applied Mechanics: an Elementary General Introduction to the Theory of Structures and Machines. By JAMES H. COTTERILL, F.R.S., Associate Member of the Council of the Institution of Naval Architects, Associate Member of the Institution of Civil Engineers, Professor of Applied Mechanics in the Royal Naval College, Greenwich. Medium 8vo. 18s.

A Text-Book of the Principles of Physics. By ALFRED DANIELL, M.A., LL.B., D.Sc., F.R.S.E., late Lecturer on Physics in the School of Medicine, Edinburgh. With Illustrations. Second Edition. Revised and Enlarged. Medium 8vo. 21s.

The Kinematics of Machinery. Outlines of a Theory of Machines. By Professor F. REULEAUX. Translated and Edited by Professor A. B. W. KENNEDY, C.E. With 450 Illustrations. Medium 8vo. 21s.

Spectrum Analysis. Lectures delivered in 1868 before the Society of Apothecaries of London. By Sir HENRY E. ROSCOE, LL.D., F.R.S., Professor of Chemistry in the Owens College, Victoria University, Manchester. Fourth Edition, revised and considerably enlarged by the Author and by ARTHUR SCHUSTER, F.R.S., Ph.D., Professor of Applied Mathematics in the Owens College, Victoria University. With Appendices, numerous Illustrations, and Plates. Medium 8vo. 21s.

Electrostatics and Magnetism. Reprints of Papers on. By Sir WILLIAM THOMSON, D.C.L., LL.D., F.R.S., F.R.S.E., Fellow of St. Peter's College, Cambridge, and Professor of Natural Philosophy in the University of Glasgow. Second Edition. Medium 8vo. 18s.

ASTRONOMY.

Popular Astronomy. By S. NEWCOMB, LL.D., Professor U.S. Naval Observatory. With 112 Illustrations and 5 Maps of the Stars. Second Edition, revised. 8vo. 18s.

CHEMISTRY.

Inorganic and Organic Chemistry. A Complete Treatise on Inorganic and Organic Chemistry. By Sir HENRY E. ROSCOE, F.R.S., and Professor C. SCHORLEMMER, F.R.S. With numerous Illustrations. Medium 8vo.

Vols. I. and II.—INORGANIC CHEMISTRY.

Vol. I.—The Non-Metallic Elements. 21s. Vol. II. Part I.—Metals. 18s. Vol. II. Part II.—Metals. 18s.

Vol. III.—ORGANIC CHEMISTRY. Three Parts.

The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. With numerous Illustrations. Medium 8vo. Parts I. and II., 21s. each. Part III., 18s.

Elements of Chemical Physics. By JOSIAH P. COOKE, Junr., Erving Professor of Chemistry and Mineralogy in Harvard University. Fourth Edition. Royal 8vo. 21s.

A Manual of the Chemistry of the Carbon COMPOUNDS, OR ORGANIC CHEMISTRY. By C. SCHORLEMMER, F.R.S., Professor of Chemistry in the Victoria University, the Owens College, Manchester. With Illustrations. 8vo. 14s.

The Elements of Thermal Chemistry. By M. M. PATTISON MUIR, M.A., F.R.S.E., Fellow and Prælector of Chemistry in Gonville and Caius College, Cambridge; Assisted by DAVID MUIR WILSON. 8vo. 12s. 6d.

BIOLOGY.

A Text-Book of Physiology. By MICHAEL FOSTER, M.D., Sec. R.S., Professor of Physiology in the University of Cambridge. With Illustrations. Fourth Edition, revised. 8vo. 21s.

Elements of the Comparative Anatomy of VERTEBRATES. Adapted from the German of ROBERT WIEDERSHEIM, Professor of Anatomy, and Director of the Institute of Human and Comparative Anatomy in the University of Freiburg-in-Baden. By W. NEWTON PARKER, Professor of Biology in the University College of South Wales and Monmouthshire. With Additions by the Author and Translator. With Two Hundred and Seventy Woodcuts. Medium 8vo. 12s. 6d.

A Treatise on Comparative Embryology. By F. M. BALFOUR, M.A., F.R.S., Fellow and Lecturer of Trinity College, Cambridge. With Illustrations. Second Edition, reprinted without alteration from the First Edition. In 2 vols. 8vo. Vol. I. 18s. Vol. II. 21s.

Elements of Comparative Anatomy. By Professor CARL GEGENBAUR. A Translation by F. JEFFREY BELL, B.A. Revised with Preface by Professor E. RAY LANKESTER, F.R.S. With numerous Illustrations. 8vo. 21s.

BIOLOGY—*continued.*

A Text-Book of the Physiological Chemistry OF THE ANIMAL BODY. Including an Account of the Chemical Changes occurring in Disease. By A. GAMGEE, M.D., F.R.S., Professor of Physiology in the Victoria University, the Owens College, Manchester. 2 Vols. 8vo. With Illustrations. Vol. I. 18s.

[*Vol. II in the press.*

The Fertilisation of Flowers. By Professor HERMANN MÜLLER. Translated and Edited by D'ARCY W. THOMPSON, B.A., Professor of Biology in University College, Dundee. With a Preface by CHARLES DARWIN, F.R.S. With numerous Illustrations. Medium 8vo. 21s.

A Dictionary of Economic Plants. Their History, Products, and Uses. By JOHN SMITH, A.L.S., &c. 8vo. 14s.

MEDICINE.

A Text-Book of Pharmacology, Thera-PEUTICS, AND MATERIA MEDICA. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.C.P., F.R.S., Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; late Examiner in the University of Edinburgh. Adapted to the United States Pharmacopœia, by FRANCIS H. WILLIAMS, M.D., Boston, Mass. Second Edition. Adapted to the New British Pharmacopœia, 1885. Medium 8vo. 21s.

Tables of Materia Medica: a Companion to the Materia Medica Museum. By the same Author. With Illustrations. New Edition Enlarged. 8vo. 10s. 6d.

Text-Book of Pathological Anatomy and PATHOGENESIS. By Professor ERNST ZIEGLER of Tubingen. Translated and Edited for English Students by DONALD MACALISTER, M.A., M.D., B.Sc., F.R.C.P., Fellow and Medical Lecturer of St. John's College, Cambridge, Physician to Addenbrooke's Hospital, and Teacher of Medicine in the University. With numerous Illustrations. Medium 8vo.

Part I.—GENERAL PATHOLOGICAL ANATOMY. 12s. 6d.

Part II.—SPECIAL PATHOLOGICAL ANATOMY. Sections I.—VIII. 12s. 6d. Sections IX.—XII. 12s. 6d.

GEOLOGY.

Text-Book of Geology. By ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland, and Director of the Museum of Practical Geology, London, formerly Murchison Professor of Geology and Mineralogy in the University of Edinburgh, &c. With numerous Illustrations. Second Edition. Fifth Thousand. Revised and Enlarged. 8vo. 28s.

A Treatise on Ore Deposits. By J. ARTHUR PHILLIPS, F.R.S., V.P.G.S., F.C.S., M.Inst.C.E., Ancien Elève de l'Ecole des Mines, Paris; Author of "A Manual of Metallurgy," "The Mining and Metallurgy of Gold and Silver," &c. With numerous Illustrations. 8vo. 25s.

POLITICAL ECONOMY.

The Principles of Political Economy. By Professor HENRY SIDGWICK, M.A., LL.D., Knightbridge Professor of Moral Philosophy in the University of Cambridge, &c., Author of "The Methods of Ethics." 8vo. 16s.

Political Economy. By FRANCIS A. WALKER, M.A., Ph.D., Author of "Money," "Money in its Relation to Trade," &c. 8vo. 10s. 6d.

MENTAL AND MORAL PHILOSOPHY.

The Methods of Ethics. By Professor HENRY SIDGWICK, M.A., LL.D. Cambridge, &c. Third Edition. 8vo. 14s. A Supplement to the Second Edition, containing all the important Additions and Alterations in the Third Edition. Demy 8vo. 6s.

Critique of Pure Reason. By IMMANUEL KANT. In commemoration of the Centenary of its first Publication. Translated into English by F. MAX MÜLLER. With an Historical Introduction by LUDWIG NOIRÉ. Two vols. Demy 8vo. 16s. each.

Vol. I. HISTORICAL INTRODUCTION, by LUDWIG NOIRÉ; &c.

Vol. II. CRITIQUE of PURE REASON, translated by F. MAX MÜLLER.

For the convenience of students these volumes are now sold separately.

Of Prof. Max Muller's translation of the "Critique of Pure Reason," the *Times* says:—"Through this translation Kant's work has for the first time become international—the common property of the whole world."

⁂ *Other Volumes to follow.*

ELECTRICAL ENGINEERING

CITY AND GUILDS OF LONDON INSTITUTE.

The Courses of Technical Instruction at the Central Institution, Exhibition Road, S.W. are open to persons desirous of studying any branch of ELECTRICAL ENGINEERING. The Instruction, under the general direction of Prof AYRTON, F R S, comprises Lectures and Practice in the Laboratories and Dynamo-Room. For particulars apply at Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS Director and Secretary

DYNAMO-ELECTRIC MACHINERY.

A Special Course of PRACTICAL DEMONSTRATIONS in the TESTING of the POWER and EFFICIENCY of DYNAMOS and MOTORS will be given by Prof. AYRTON, F.R.S., at the CENTRAL INSTITUTION of the CITY and GUILDS of LONDON INSTITUTE, commencing on FRIDAY, February 4, at 5 p.m. For particulars apply at Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

BERKHAMPSTED SCHOOL, HERTS. Twenty-eight miles from Euston. Good Scholarships and Exhibitions. Laboratory, heated swimming-bath, workshop, &c. £52 per annum.—Address, Head-Master.

FATAL GAP in SCIENTIFIC LITERATURE.—Educated and intelligent men, who profess a certain knowledge of current topics, will read the last new Journal—"THE EARTH"—with shame and confusion at the discovery of their absolute ignorance of the most elementary principles of Physical Science, and that what they do know they know all wrong.—29, Paternoster Row. 1d.

LATITUDES and LONGITUDES and SOLAR COURSES, together with a Coloured and Highly Finished MAP of the WORLD, both of them compiled on the only correct principle ever published or procurable. 1s. 6d. to EDITOR, Cosmos House, Balham, Surrey.

SHELLS.—Two Ten-Drawer Imitation Mahogany Cabinets, containing 765 Species of British and Foreign Shells (about 1500 Specimens), also about 500 other Specimens of Red Crag Fossils, Fossil Teeth (100 Species), Birds' Eggs, and Marine Animals in Spirit—making, in all, 2000 Specimens. Owner must part with this collection at once, as he is going abroad. £25.—Address ALPHA, Beech Cottage, 2, Wellington Road, Bow, London, E.

GAS, INSURANCE, BANK, CITY R.R. STOCKS of NEW YORK and BROOKLYN. Send for Weekly List and Annual Tables of Range of Prices and Dividends, ready shortly.—J. P. WINTRINGHAM, 36, Pine Street, New York, U.S.A.

The NEW ATHENÆUM CLUB (Scientific, Literary, and Social) has VACANCIES for a limited number of ADDITIONAL MEMBERS without Entrance Fee.—Particulars, with List of Vice-Presidents and Committee, will be forwarded on application to the SECRETARY, 26, Suffolk Street, Pall-Mall.

BOOKS (Secondhand), Miscellaneous, Remainders, &c.—C. HERBERT, English and Foreign Bookseller, 319, Goswell Road, London, E.C. Catalogue free on receipt of two stamps. Libraries, Old Books, and Parchments purchased.

ZEISS MICROSCOPE STANDS in STOCK in handsome Nickel mounted Cabinets. Verified Objectives, ordinary and the new Apochromatic. List, W. HUME, Optician, Lothian Street, Edinburgh.

YORK'S

OPTICAL LANTERN SLIDES.

Seven Medals have been awarded.

In addition to the thousands of subjects, embracing Travel, every branch of Science, &c., &c., and the much appreciated Popular Recitations, Moral, Comic, and Temperance Tales illustrated by Life Models, the following are added to their seventeenth Annual Catalogue:—

Washington to the Yellowstone Park, Washington City; English and Italian Lakes; Venice; Algiers; Holland; Burmah; Channel Islands; Norway; the Improved Comic Slips; and the following from Life Models—"Curfew must not Ring To-night," and the popular Temperance Tale, "Little Tim."

Sold by all the Leading Opticians in the United Kingdom, through whom please order.

YORK & SON,

87, Lancaster Road, Notting Hill, London, W.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM, Who last week sent to his Subscribers Stephanoceros Eichornii, with drawing and description. He also sent out Floscularia campanulata, Floscularia cornuta, Cephalosiphon limnias, Melicerta ringens, Brachionus urceolaris, Eurycercus lamellatus, Sida crystallina, Argulus foliaceus, Difflugia, Desmids, Volvox globator, also Hydra, Amœba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s. or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

MINERALS AND STONE IMPLEMENTS.

MR. BRYCE-WRIGHT begs to call the attention of his Clients and the Public to his large Series of

MINERALS AND STONE IMPLEMENTS,

from which single specimens can be selected.

Elementary Collections of Minerals, Fossils, and Rocks from £1 upwards.

N.B.—These Collections obtained the Prize Medal, 1862.

GEMS AND PRECIOUS STONES OF EVERY DESCRIPTION.

BRYCE-WRIGHT,

Mineralogist and Expert in Precious Stones,

THE MECHANICS OF MACHINERY. By ALEX. B. W. KENNEDY, C.E., Professor of Civil and Mechanical Engineering in University College, London. With Illustrations. Crown 8vo. 12s. 6d.

CHEMISTRY.

THE STUDY OF CHEMISTRY, AN INTRODUCTION TO. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

COMPOUNDS OF CARBON; or, Organic Chemistry, an Introduction to the Study of. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

BIOLOGY.

THE ELEMENTS OF EMBRYOLOGY. By MICHAEL FOSTER, M.A., M.D., LL.D., Sec. R.S., Professor of Physiology in the University of Cambridge, Fellow of Trinity College, Cambridge, and the late FRANCIS M. BALFOUR, M.A., LL.D., F.R.S., Fellow of Trinity College, Cambridge, and Professor of Animal Morphology in the University. Second Edition, revised. Edited by ADAM SEDGWICK, M.A., Fellow and Assistant Lecturer of Trinity College, Cambridge, and WALTER HEAPE, Demonstrator in the Morphological Laboratory of the University of Cambridge. Illustrated. 10s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN ELEMENTARY BIOLOGY. By THOMAS HENRY HUXLEY, F.R.S., assisted by H. N. MARTIN, M.B., D.Sc. New Edition, revised. Crown 8vo. 6s.

A COURSE OF ELEMENTARY PRACTICAL PHYSIOLOGY. By Prof. MICHAEL FOSTER, M.D., Sec. R.S., &c., and J. N. LANGLEY, M.A., F.R.S., Fellow of Trinity College, Cambridge. Fifth Edition. Crown 8vo. 7s. 6d.

AN INTRODUCTION TO THE OSTEOLOGY OF THE MAMMALIA. By WILLIAM HENRY FLOWER, LL.D., F.R.S., Director of the Natural History Departments of the British Museum, late Hunterian Professor of Comparative Anatomy and Physiology in the Royal College of Surgeons of England. With numerous Illustrations. Third Edition. Revised with the assistance of HANS GADOW, Ph.D., M.A., Lecturer on the Advanced Morphology of Vertebrates and Strickland Curator in Univ. of Camb. Cr. 8vo. 10s. 6d.

AN ATLAS OF PRACTICAL ELEMENTARY BIOLOGY. By G. B. HOWES, Assistant Professor of Zoology, Normal School of Science and Royal School of Mines. With a Preface by THOMAS HENRY HUXLEY, F.R.S. Royal 4to. 14s.

A COURSE OF INSTRUCTION IN ZOOTOMY (VERTEBRATA). By T. JEFFREY PARKER, B.Sc. London, Professor of Biology in the University of Otago, New Zealand. With Illustrations. Crown 8vo. 8s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, M.A., F.L.S., Professor of Botany in the University of Glasgow, and SYDNEY H. VINES, M.A., D.Sc., F.R.S., Fellow and Lecturer, Christ's College, Cambridge. With a Preface by W. T. THISELTON DYER, M.A., C.M.G., F.R.S., F.L.S., Director of the Royal Gardens, Kew.

Part I.—PHANEROGAMÆ—PTERIDOPHYTA. Crown 8vo. 6s.

STRUCTURAL BOTANY, OR ORGANOGRAPHY ON THE BASIS OF MORPHOLOGY. To which are added the Principles of Taxonomy and Phytography, and a Glossary of Botanical Terms. By Professor ASA GRAY, LL.D. 8vo. 10s. 6d.

THE STUDENT'S FLORA OF THE BRITISH ISLANDS. By Sir J. D. HOOKER, K.C.S.I., C.B., M.D., F.R.S., D.C.L. Third Edition, revised. Globe 8vo. 10s. 6d.

FIRST BOOK OF INDIAN BOTANY. By DANIEL OLIVER, F.R.S., &c., Professor of Botany in University College, London, &c. With Illustrations. Extra fcap. 8vo. 6s. 6d.

DOMESTIC BOTANY: An Exposition of the Structure and Classification of Plants, and their Uses for Food, Clothing, Medicine, and Manufacturing Purposes. By JOHN SMITH, A.L.S., &c. With Illustrations. New Issue. Crown 8vo. 12s. 6d.

EUROPEAN BUTTERFLIES, A HANDBOOK OF. By W. F. DE VISMES KANE, M.A., M.R.I.A., Member of the Entomological Society of London, &c. With Copper Plate Illustrations. Crown 8vo. 10s. 6d.

A LIST OF EUROPEAN RHOPALOCERA, WITH THEIR VARIETIES AND PRINCIPAL SYNONYMS. Reprinted from the *Handbook of European Butterflies*. Crown 8vo. 1s.

MEDICINE.

MICRO-ORGANISMS AND DISEASE. An Introduction into the Study of Specific Micro-Organisms. By E. KLEIN, M.D., F.R.S., Lecturer on General Anatomy and Physiology in the Medical School of St. Bartholomew's Hospital, London. With 121 Illustrations. Third Edition. Revised. Crown 8vo. 6s.

ANTHROPOLOGY.

ANTHROPOLOGY. An Introduction to the Study of Man and Civilisation. By E. B. TYLOR, D.C.L., F.R.S. With numerous Illustrations. Crown 8vo. 7s. 6d.

PHYSIOGRAPHY AND GEOLOGY.

PHYSIOGRAPHY. An Introduction to the Study of Nature. By THOMAS HENRY HUXLEY, F.R.S. With numerous Illustrations, and Coloured Plates. New and Cheaper Edition. Crown 8vo. 6s.

CLASS-BOOK OF GEOLOGY. By ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland, and Director of the Museum of Practical Geology, London, formerly Murchison Professor of Geology and Mineralogy in the University of Edinburgh, &c. With upwards of 200 New Illustrations. Crown 8vo. 10s. 6d.

AGRICULTURE.

AGRICULTURAL CHEMICAL ANALYSIS, A Handbook of. By PERCY FARADAY FRANKLAND, Ph.D., B.Sc., F.C.S., Associate of the Royal School of Mines, and Demonstrator of Practical and Agricultural Chemistry in the Normal School of Science and Royal School of Mines, South Kensington Museum. Founded upon *Leitfaden für die Agricultur-Chemische Analyse*, von Dr. F. KROCKER. Crown 8vo. 7s. 6d.

POLITICAL ECONOMY.

A MANUAL OF POLITICAL ECONOMY. By Right Hon. HENRY FAWCETT, F.R.S. Sixth Edition, revised, with a chapter on "State Socialism and the Nationalisation of the Land," and an Index. Crown 8vo. 12s.

A BRIEF TEXT-BOOK OF POLITICAL ECONOMY. By FRANCIS A. WALKER, M.A., Ph.D., Author of "Money," "Money in its Relation to Trade," &c. Crown 8vo. 6s. 6d.

MORAL PHILOSOPHY AND LOGIC.

THE HISTORY OF ETHICS, OUTLINES OF, FOR ENGLISH READERS. By HENRY SIDGWICK, M.A., LL.D., Knightbridge Professor of Moral Philosophy in the University of Cambridge, Author of "The Methods of Ethics," "The Principles of Political Economy," &c. Crown 8vo. 3s. 6d.

THE ELEMENTS OF THE PSYCHOLOGY OF COGNITION. By the Rev. ROBERT JARDINE, B.D., D.Sc. (Edin.), Ex-Principal of the General Assembly's College, Calcutta. Second Edition, revised and improved. Crown 8vo. 6s. 6d.

STUDIES IN DEDUCTIVE LOGIC. By the late W. STANLEY JEVONS, LL.D., M.A., F.R.S. Second Edition. Crown 8vo. 6s.

ANCIENT GEOGRAPHY.

MANUAL OF ANCIENT GEOGRAPHY. Translated from the German of Dr. HEINRICH KIEPERT. Crown 8vo. 5s.

HISTORY.

SHORT HISTORY OF THE ENGLISH PEOPLE. By JOHN RICHARD GREEN, M.A., LL.D., late Honorary Fellow of Jesus College, Oxford. With Coloured Maps, Genealogical Tables, and Chronological Annals. Crown 8vo. 8s. 6d. 117th Thousand.

ANALYSIS OF ENGLISH HISTORY, based on Green's "Short History of the English People." By C. W. A. TAIT, M.A., Assistant Master, Clifton College. Crown 8vo. 3s. 6d.

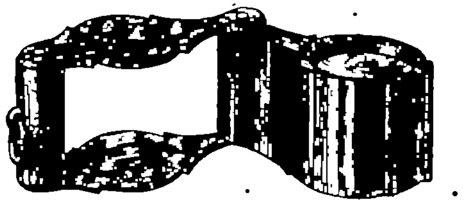
BROWNING'S PLATYSCOPIC LENS.



Engraved Real Size.
A NEW ACHROMATIC COMBINATION,
COMBINING THE DEFINITION OF A MICROSCOPE WITH THE PORTABILITY OF A POCKET LENS.

"If you carry a small Platyscopic Pocket Lens (which every observer of Nature ought to do)."—Grant Allen in *Knowledge*.

The Platyscopic Lens is invaluable to botanists, mineralogists, or entomologists, as it focusses about three times as far from the object as the Coddington Lenses. This allows opaque objects to be examined easily.

The Platyscopic Lens is made of four degrees of power, magnifying respectively 10, 15, 20, and 30 diams.; the lowest power, having the largest field, is the best adapted for general use.

The Lenses are set in Ebonite Cells, and mounted in Tortoiseshell Frames.

Price of the Platyscopic Lens, mounted in Tortoiseshell, magnifying either 10, 15, 20, *or* 30 *diameters*, 18*s*. 6*d*. *each power.*

Illustrated description sent free.

CHRISTMAS LECTURES.

LECTURE HOUR 3 o'clock p.m.

Prof. DEWAR, M.A., F.R.S., M.R.I. Six Lectures (adapted to a Juvenile Auditory) on "The Chemistry of Light and Photography" (with Experimental Illustrations). On December 28 (Tuesday), December 30, 1886; January 1, 4, 6, 8, 1887. One Guinea the Course; Children under 16, Half-a-Guinea.

AFTERNOON LECTURES BEFORE EASTER, 1887.

LECTURE HOUR 3 o'clock p.m.

Prof ARTHUR GAMGEE, M.D., F.R.S. Eleven Lectures on "The Function of Respiration." On Tuesdays, January 18 to March 29. One Guinea.

Prof. A. W. RÜCKER, M.A., F.R.S., M.R.I. Five Lectures on "Molecular Forces." On Thursdays, January 20, 27, February 3, 10, 17. Half-a-Guinea.

EDMUND GOSSE, Esq., M.A., Clark Lecturer in English Literature, Trinity College, Cambridge. Three Lectures on "The Critics of the Age of Anne." On Thursdays, February 24, March 3, 10. Half-a-Guinea.

Prof. F. MAX MÜLLER, M.A., LL.D. Three Lectures on "The Science of Thought." On Thursdays, March 17, 24, 31. Half-a-Guinea.

CARL ARMBRUSTER, Esq. Five Lectures on "Modern Composers of Classical Song." On Saturdays, January 22, 29, February 5, 12, 19. One Guinea.

The RIGHT HON. LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.S., M.R.I. Six Lectures on "Sound." On Saturdays, February 26, March 5, 12, 19, 26, April 2. One Guinea.

Subscription (to Non-Members) to all the Courses during the Season, Two Guineas. Tickets issued daily at the Institution, or sent by Post on receipt of Cheque or Post-Office Order.

Members may purchase not less than Three Single Lecture Tickets, available for any Lecture, for Half-a-Guinea.

The Friday Evening Meetings will begin on January 21, at 3 p.m., when SIR WILLIAM THOMSON will give a Discourse on "The Probable Origin, the Total Amount, and the Possible Duration of the Sun's Heat," at 9 p.m. Succeeding Discourses will probably be given by Mr. W. BALDWIN SPENCER, Mr. E. FRESHFIELD, Mr. E. B. POULTON, Mr. W. CROOKES, CAPTAIN ABNEY, Mr. VICTOR HORSLEY, VEN. ARCHDEACON FARRAR, Mr. G. J. ROMANES, the RIGHT HON. LORD RAYLEIGH and other gentlemen. To these Meetings Members and their Friends only are admitted.

Persons desirous of becoming Members are requested to apply to the Secretary. When proposed they are immediately admitted to all the Lectures, to the Friday Evening Meetings, and to the Library and Reading Rooms; and their Families are admitted to the Lectures at a reduced charge. Payment: First Year, Ten Guineas; afterwards, Five Guineas a Year; or a composition of Sixty Guineas.

CHEMISTRY OF THE ALKALOIDS, ETC.

CITY AND GUILDS OF LONDON INSTITUTE.

Prof ARMSTRONG, F.R.S., will commence a Course of about Twenty Lectures on January 27, 1887, at the CENTRAL INSTITUTION, Exhibition Road, S.W., on the CHEMISTRY of NITROGEN and its COMPOUNDS, with Special Reference to Recent Investigations of the ALKALOIDS, ALBUMENOIDS, &c. The Lectures will be given at 5 p.m. on MONDAYS and WEDNESDAYS. Fee for the Course, £1 1s. For further particulars apply at the Central Institution, Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

CHEMICAL ENGINEERING.

CITY AND GUILDS OF LONDON INSTITUTE.

Course of Technical Instruction for Chemists, Manufacturers, and others, including Practice in Chemical Engineering and Physical Laboratories, under the direction of Prof. ARMSTRONG, Ph.D., F.R.S.

For particulars apply at the CENTRAL INSTITUTION, Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

ENGINEERING.

CITY AND GUILDS OF LONDON INSTITUTE.

The Courses of Technical Instruction at the Central Institution, Exhibition Road, S.W., are open to persons desirous of studying CIVIL or MECHANICAL ENGINEERING.

The Instruction, under the general direction of Prof UNWIN, F.R.S., M.Inst.C.E., comprises LECTURES on the Principles of ENGINEERING; LESSONS in Drawing and in the Designing of MACHINES and STRUCTURES; Practice in the WORKSHOP, and Experiments in the Engineering Laboratory on the STRENGTH of MATERIALS, and on the Efficiency of the STEAM-ENGINE.

For particulars apply at Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

BOOKS (Secondhand), Miscellaneous, Remainders, &c.—C. HERBERT, English and Foreign Bookseller, 319, Goswell Road, London, E.C. Catalogue free on receipt of two stamps. Libraries, Old Books, and Parchments purchased.

OUR MORALITY AND THE MORAL QUESTION. By LIONEL BEALE, F.R S., Professor of Medicine in King's College, London.

J & A CHURCHILL

NORTH BRITISH AGRICULTURIST,

the chief Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 14s.

MESSRS. MACMILLAN AND CO.'S

TEXT-BOOKS FOR STUDENTS.

NATURAL PHILOSOPHY.

Applied Mechanics: an Elementary General Introduction to the Theory of Structures and Machines. By JAMES H. COTTERILL, F.R.S., Associate Member of the Council of the Institution of Naval Architects, Associate Member of the Institution of Civil Engineers, Professor of Applied Mechanics in the Royal Naval College, Greenwich. Medium 8vo. 18s.

A Text-Book of the Principles of Physics. By ALFRED DANIELL, M.A., LL.B., D.Sc., F.R.S.E., late Lecturer on Physics in the School of Medicine, Edinburgh. With Illustrations. Second Edition. Revised and Enlarged. Medium 8vo. 21s.

The Kinematics of Machinery. Outlines of a Theory of Machines. By Professor F. REULEAUX. Translated and Edited by Professor A. B. W. KENNEDY, C.E. With 450 Illustrations. Medium 8vo. 21s.

Spectrum Analysis. Lectures delivered in 1868 before the Society of Apothecaries of London. By Sir HENRY E. ROSCOE, LL.D., F.R.S., Professor of Chemistry in the Owens College, Victoria University, Manchester. Fourth Edition, revised and considerably enlarged by the Author and by ARTHUR SCHUSTER, F.R.S., Ph.D., Professor of Applied Mathematics in the Owens College, Victoria University. With Appendices, numerous Illustrations, and Plates. Medium 8vo. 21s.

Electrostatics and Magnetism. Reprints of Papers on. By Sir WILLIAM THOMSON, D.C.L., LL.D., F.R.S., F.R.S.E., Fellow of St. Peter's College, Cambridge, and Professor of Natural Philosophy in the University of Glasgow. Second Edition. Medium 8vo. 18s.

ASTRONOMY.

Popular Astronomy. By S. NEWCOMB, LL.D., Professor U.S. Naval Observatory. With 112 Illustrations and 5 Maps of the Stars. Second Edition, revised. 8vo. 18s.

CHEMISTRY.

Inorganic and Organic Chemistry. A Complete Treatise on Inorganic and Organic Chemistry. By Sir HENRY E. ROSCOE, F.R.S., and Professor C. SCHORLEMMER, F.R.S. With numerous Illustrations. Medium 8vo.

Vols. I. and II.—INORGANIC CHEMISTRY.

Vol. I.—The Non-Metallic Elements. 21s. Vol. II. Part I.—Metals. 18s. Vol. II. Part II.—Metals. 18s.

Vol. III.—ORGANIC CHEMISTRY. Three Parts.

The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. With numerous Illustrations. Medium 8vo. Parts I. and II., 21s. each. Part III., 18s.

Elements of Chemical Physics. By JOSIAH P. COOKE, Junr., Erving Professor of Chemistry and Mineralogy in Harvard University. Fourth Edition. Royal 8vo. 21s.

A Manual of the Chemistry of the Carbon COMPOUNDS, OR ORGANIC CHEMISTRY. By C. SCHORLEMMER, F.R.S., Professor of Chemistry in the Victoria University, the Owens College, Manchester. With Illustrations. 8vo 14s.

The Elements of Thermal Chemistry. By M. M. PATTISON MUIR, M.A., F.R.S.E., Fellow and Prælector of Chemistry in Gonville and Caius College, Cambridge; Assisted by DAVID MUIR WILSON. 8vo. 12s. 6d.

BIOLOGY.

A Text-Book of Physiology. By MICHAEL FOSTER, M.D., Sec. R.S., Professor of Physiology in the University of Cambridge. With Illustrations. Fourth Edition, revised. 8vo. 21s.

Elements of the Comparative Anatomy of VERTEBRATES. Adapted from the German of ROBERT WIEDERSHEIM, Professor of Anatomy, and Director of the Institute of Human and Comparative Anatomy in the University of Freiburg-in-Baden. By W. NEWTON PARKER, Professor of Biology in the University College of South Wales and Monmouthshire. With Additions by the Author and Translator. With Two Hundred and Seventy Woodcuts. Medium 8vo. 12s. 6d.

A Treatise on Comparative Embryology. By F. M. BALFOUR, M.A., F.R.S., Fellow and Lecturer of Trinity College, Cambridge. With Illustrations. Second Edition, reprinted without alteration from the First Edition. In 2 vols. 8vo. Vol. I. 18s. Vol. II. 21s.

Elements of Comparative Anatomy. By Professor CARL GEGENBAUR. A Translation by F. JEFFREY BELL, B.A. Revised with Preface by Professor E. RAY LANKESTER, F.R.S. With numerous Illustrations. 8vo. 21s.

BIOLOGY—*continued.*

A Text-Book of the Physiological Chemistry OF THE ANIMAL BODY. Including an Account of the Chemical Changes occurring in Disease. By A. GAMGEE, M.D., F.R.S., Professor of Physiology in the Victoria University, the Owens College, Manchester. 2 Vols. 8vo. With Illustrations. Vol. I. 18s. [*Vol. II. in the press*

The Fertilisation of Flowers. By Professor HERMANN MÜLLER. Translated and Edited by D'ARCY W. THOMPSON, B.A., Professor of Biology in University College, Dundee. With a Preface by CHARLES DARWIN, F.R.S. With numerous Illustrations. Medium 8vo. 21s.

A Dictionary of Economic Plants. Their History, Products, and Uses. By JOHN SMITH, A.L.S., &c. 8vo. 14s.

MEDICINE.

A Text-Book of Pharmacology, TheraPEUTICS, AND MATERIA MEDICA. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.C.P., F.R.S., Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; late Examiner in the University of Edinburgh. Adapted to the United States Pharmacopœia, by FRANCIS H. WILLIAMS, M.D., Boston, Mass. Second Edition. Adapted to the New British Pharmacopœia, 1885. Medium 8vo. 21s.

Tables of Materia Medica: a Companion to the Materia Medica Museum. By the same Author. With Illustrations. New Edition Enlarged. 8vo. 10s. 6d.

Text-Book of Pathological Anatomy and PATHOGENESIS. By Professor ERNST ZIEGLER of Tübingen. Translated and Edited for English Students by DONALD MACALISTER, M.A., M.D., B.Sc., F.R.C.P., Fellow and Medical Lecturer of St. John's College, Cambridge, Physician to Addenbrooke's Hospital, and Teacher of Medicine in the University. With numerous Illustrations. Medium 8vo

Part I.—GENERAL PATHOLOGICAL ANATOMY. 12s. 6d.

Part II.—SPECIAL PATHOLOGICAL ANATOMY. Sections I.—VIII. 12s. 6d. Sections IX.—XII. 12s. 6d.

GEOLOGY.

Text-Book of Geology. By ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland, and Director of the Museum of Practical Geology, London, formerly Murchison Professor of Geology and Mineralogy in the University of Edinburgh, &c. With numerous Illustrations. Second Edition. Fifth Thousand. Revised and Enlarged. 8vo. 28s.

A Treatise on Ore Deposits. By J. ARTHUR PHILLIPS, F.R.S., V.P.G.S., F.C.S., M.Inst.C.E., Ancien Elève de l'Ecole des Mines, Paris, Author of "A Manual of Metallurgy," "The Mining and Metallurgy of Gold and Silver," &c. With numerous Illustrations. 8vo. 25s.

POLITICAL ECONOMY.

The Principles of Political Economy. By Professor HENRY SIDGWICK, M.A., LL.D., Knightbridge Professor of Moral Philosophy in the University of Cambridge, &c., Author of "The Methods of Ethics." 8vo. 16s.

Political Economy. By FRANCIS A. WALKER, M.A., Ph.D., Author of "Money," "Money in its Relation to Trade," &c. 8vo. 10s. 6d.

MENTAL AND MORAL PHILOSOPHY.

The Methods of Ethics. By Professor HENRY SIDGWICK, M.A., LL.D. Cambridge, &c. Third Edition. 8vo. 14s. A Supplement to the Second Edition, containing all the important Additions and Alterations in the Third Edition. Demy 8vo. 6s.

Critique of Pure Reason. By IMMANUEL KANT. In commemoration of the Centenary of its first Publication. Translated into English by F. MAX MÜLLER. With an Historical Introduction by LUDWIG NOIRÉ. Two vols. Demy 8vo 16s. each.

Vol. I. HISTORICAL INTRODUCTION, by LUDWIG NOIRÉ; &c.

Vol. II. CRITIQUE of PURE REASON, translated by F. MAX MÜLLER.

For the convenience of students these volumes are now sold separately.

Of Prof. Max Müller's translation of the "Critique of Pure Reason," the *Times* says:—"Through this translation Kant's work has for the first time become international—the common property of the whole world."

⁂ *Other Volumes to follow.*

MACMILLAN & CO., LONDON.

Printed by RICHARD CLAY AND SONS, at 7 and 8, Bread Street Hill, Queen Victoria Street, in the City of London, and Published by MACMILLAN AND CO., at the Office, 29 and 30 Bedford Street, Covent Garden.—THURSDAY, December 23, 1886.

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH

No. 896, Vol. 35] THURSDAY, DECEMBER 30, 1886 [Price Sixpence

Registered as a Newspaper at the General Post Office] [All Rights are Reserved

R. & J. BECK, 68, Cornhill, London, E.C.
GOLD MEDAL,
International Inventions Exhibition, 1885.

SEISMOGRAPHS
From the Designs of Prof. J. A. EWING.

Horizontal Pendulum Seismograph, to record two components of horizontal motion on a revolving plate, with glass plate, driving-clock, and electric seismoscope to start the clock.

Clock to mark time on the revolving plate and to show the hour and minute at which an earthquake occurs.

Vertical Motion Seismograph, to record the vertical component of the earth's motion on the same revolving plate as the above

Duplex Pendulum Seismograph, to record the whole horizontal motion of the ground (in all azimuths) on a fixed plate (This instrument is complete in itself.)

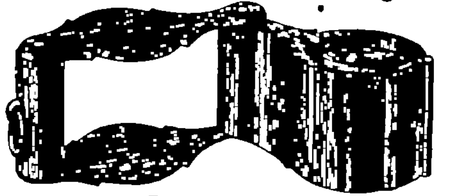
A fully-illustrated Description will be sent on application.

The CAMBRIDGE SCIENTIFIC INSTRUMENT COMPANY,
Cambridge.

ROCKS, MINERALS, FOSSILS.
F. H. BUTLER,
Assoc. R. S. Mines Lond., M.A. Oxon., L.S.A. Lond., &c.,
Successor to the late R. TALLING,
180, BROMPTON ROAD, LONDON, S.W.

Just Received:—A large series of Palæozoic and Mesozoic Fossils from a well-known collection, all in fine preservation; also a varied assortment of mounted Foraminifera, and of new or little known Cornish and Highland Rocks. Mineral Lists shortly ready.

BROWNING'S PLATYSCOPIC LENS.



Engraved Real Size

A NEW ACHROMATIC COMBINATION,
COMBINING THE DEFINITION OF A MICROSCOPE WITH THE PORTABILITY OF A POCKET LENS.

"If you carry a small Platyscopic Pocket Lens (which every observer of Nature ought to do)"—Grant Allen in *Knowledge*.

The Platyscopic Lens is invaluable to botanists, mineralogists, or entomologists, as it focuses about three times as far from the object as the Coddington Lenses. This allows opaque objects to be examined easily.

The Platyscopic Lens is made of four degrees of power, magnifying respectively 10, 15, 20, and 30 diams., the lowest power, having the largest field, is the best adapted for general use.

The Lenses are set in Ebonite Cells, and mounted in Tortoiseshell Frames.

Price of the Platyscopic Lens; mounted in Tortoiseshell, magnifying either 10, 15, 20, *or* 30 *diameters*, 18*s.* 6*d. each power.*

Illustrated description sent free.

JOHN BROWNING, 63, STRAND, LONDON, W.C.

Negretti & Zambra's Christmas Presents.

UNIVERSITY COLLEGE, LONDON.

GEOLOGY AND MINERALOGY.

Prof BONNEY will commence a Course of about Sixty Lectures on GEOLOGY on Tuesday, January 11, at 12 Noon.

Also a Course of about Twenty Lectures on the Economic Aspects of Geology (for Students of Engineering), on Friday, January 14, at 2 p.m.

Instruction is given at other times in Microscopic Petrology and Museum and Field Work. For further particulars apply to

J. M. HORSBURGH M.A., Secretary.

UNIVERSITY COLLEGE, LONDON.

ORGANIC CHEMISTRY.

A Course of Thirty Lectures on "The Derivatives of Benzene" will be given by Dr H FORSTER MORLEY during the Second Term, beginning Wednesday, January 12, at 9 a.m. Fee, £2 12s. 6d. Ladies admitted.

J. M HORSBURGH, M A., Secretary.

WEYMOUTH COLLEGE.

Head Master . . . . Rev. JOHN MILLER, B.D.

The Distinctions gained direct from the School during the past year include :—

Tenth Place, India Civil Service; Third Place for Commissions in Royal Engineers; several Open Scholarships and Exhibitions at the Universities

In the July Examination of the Oxford and Cambridge Joint Boards, the only Distinctions gained in Biology and Botany were awarded to this School.

Fees, inclusive, from Sixty Guineas a year.

There will be an Examination for not less than three Entrance Scholarships, worth £40 a year, on Friday, January [illegible]. For all particulars, apply to the HEAD MASTER

BEDFORD COLLEGE, LONDON

(FOR LADIES),

8 AND 9, YORK PLACE, BAKER STREET, W.

LENT TERM will begin on Thursday. January 20, 1887. Mr J. S. MANN, of Trinity College, Oxford, will give a Course of Lectures on POLITICAL ECONOMY, on Thursdays at 2 50.

B SHADWELL, Hon. Sec.

BERKHAMPSTED SCHOOL, HERTS.

Twenty-eight miles from Euston Good Scholarships and Exhibitions. Laboratory, heated swimming-bath, workshop, &c. £52 per annum.—Address, Head-Master.

TERRESTRIAL MOTION IMPOSSIBLE.

General Drayson checkmated; the reviewers nonplussed; the professors bewildered, the public aghast. Read the January Number of *The Earth.* One Penny.—[illegible], Paternoster Row.

YORK'S
OPTICAL LANTERN SLIDES.

MARVELLOUS MEMORY DISCOVERY

(UNLIKE MNEMONICS),

And Cure of Mind Wandering.

Any Book Learned in One Reading. Great Inducements to Correspondence Classes.

New Prospectus from Prof. LOISETTE, 37, New Oxford Street, London.

THE ENTOMOLOGIST'S MONTHLY MAGAZINE.

Price Sixpence, Monthly, 24 pages 8vo, with occasional Illustrations. Conducted by C. G. BARRETT, J. W. DOUGLAS, R. McLACHLAN, F.R.S., E. SAUNDERS, F.L.S., and H. T. STAINTON, F.R.S.

This Magazine, commenced in 1864, contains standard articles and notes on all subjects connected with Entomology, and especially on the Insects of the British Isles.

Subscription—Six Shillings per Volume, post free. The volumes commence with the June number in each year.

Vols. I. to VI. (strongly bound in cloth) may be obtained by purchasers of the entire set to date, at the increased price of 10s. each; the succeeding vols. may be had separately or together, at 7s. each.

London: JOHN VAN VOORST, 1, Paternoster Row.

N.B.—Communications, &c., should be sent to the Editors at the above address.

A FRENCH GENTLEMAN, with First-rate Scholastic Recommendations, has a French Class for Army Pupils at 2, Colville Gardens, Bayswater. He and his wife also receive as Boarders two or three Young Men who wish to study the language for business or conversational purposes.—Address M. ALFRED VIZIER, Swanley, Kent.

Crown 8vo, pp. 200, 2s. 6d.

OUR MORALITY AND THE MORAL QUESTION. By LIONEL BEALE, F.R.S., Professor of Medicine in King's College, London.

J. & A. CHURCHILL.

NORTH BRITISH AGRICULTURIST,

the chief Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 14s.

Offices—377, High Street, Edinburgh; and 145, Queen Victoria Street, London, E.C. Money Orders payable to C. and R. ANDERSON.

THE ZOOLOGIST:

A MONTHLY MAGAZINE OF NATURAL HISTORY.

Third Series. Edited by J. E. HARTING, F.L.S., F.Z.S., Member of the British Ornithologists' Union; contains—

Original Articles by well-known Naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds, occurrence of rare birds, distribution and migration of British fresh-water fish; new or rare marine fish, local aquaria; British reptiles; British land and fresh-water mollusca, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts.

JOHN VAN VOORST, 1, Paternoster Row.

On the 1st of every Month, price Sixpence.

THE ENTOMOLOGIST:

AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOGY.

Edited by JOHN T. CARRINGTON,

With the Assistance of

FREDERICK BOND, F.Z.S. | RICHARD SOUTH.
EDWARD A. FITCH, F.L.S. | J. JENNER WEIR, F.L.S.
F. BUCHANAN WHITE, M.D.

Contains Articles by well-known Entomologists on all Branches of the Science; on Insects injurious or beneficial to Farm or Garden; Notes on Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthly Lists of Duplicates and Desiderata.

WOODCUT ILLUSTRATIONS and occasional LITHOGRAPHED and CHROMO-LITHOGRAPHED PLATES.

VAN HOUTEN'S

pure soluble COCOA

is the best and although a little dearer really the cheapest in the end.

The *British Medical Journal* says:—"'VAN HOUTEN'S COCOA' is admirable. In flavour it is perfect, and it is so pure, well prepared, and rich," &c. &c.

MESSRS. MACMILLAN & CO.'S MANUALS FOR STUDENTS.

NATURAL PHILOSOPHY.

ELEMENTARY PRACTICAL PHYSICS, LESSONS IN. By Professor BALFOUR STEWART, F.R.S., and W. W. HALDANE GEE, B.Sc. Crown 8vo.

Part I.—GENERAL PHYSICAL PROCESSES. 6s.

Part II.—ELECTRICITY AND MAGNETISM. [*In the press.*

Part III.—OPTICS, HEAT, AND SOUND. [*In preparation.*

A SCHOOL COURSE OF PRACTICAL PHYSICS. By the same Authors. [*In preparation.*

ON LIGHT. Being the Burnett Lectures, delivered in Aberdeen in 1883-1885. By GEORGE GABRIEL STOKES, M.A., P.R.S., &c., Fellow of Pembroke College, and Lucasian Professor of Mathematics in the University of Cambridge. First Course. ON THE NATURE OF LIGHT.—Second Course ON LIGHT AS A MEANS OF INVESTIGATION. Crown 8vo 2s. 6d. each.

THIRD COURSE. ON THE BENEFICIAL EFFECTS OF LIGHT. [*In the press.*

MECHANICAL THEORY OF HEAT. By R. CLAUSIUS. Translated by WALTER R. BROWNE, M.A., late Fellow of Trinity College, Cambridge. Crown 8vo. 10s. 6d.

HEAT. By P. G. TAIT, M.A., Sec. R.S.E., formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh. Crown 8vo 6s.

LIGHT; A COURSE OF EXPERIMENTAL OPTICS, CHIEFLY WITH THE LANTERN. By LEWIS WRIGHT. With 200 Engravings and Coloured Plates. Cr. 8vo. 7s. 6d.

MECHANICS.

THE MECHANICS OF MACHINERY. By ALEX B. W. KENNEDY, C.E., Professor of Civil and Mechanical Engineering in University College, London. With Illustrations. Crown 8vo. 12s. 6d.

CHEMISTRY.

THE STUDY OF CHEMISTRY, AN INTRODUCTION TO. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

COMPOUNDS OF CARBON; or, Organic Chemistry, an Introduction to the Study of. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

BIOLOGY.

THE ELEMENTS OF EMBRYOLOGY. By MICHAEL FOSTER, M.A., M.D., LL.D., Sec. R.S., Professor of Physiology in the University of Cambridge, Fellow of Trinity College, Cambridge, and the late FRANCIS M. BALFOUR, M.A., LL.D., F.R.S., Fellow of Trinity College, Cambridge, and Professor of Animal Morphology in the University. Second Edition, revised. Edited by ADAM SEDGWICK, M.A., Fellow and Assistant Lecturer of Trinity College, Cambridge, and WALTER HEAPE, Demonstrator in the Morphological Laboratory of the University of Cambridge. Illustrated. 10s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN ELEMENTARY BIOLOGY. By THOMAS HENRY HUXLEY, F.R.S., assisted by H. N. MARTIN, M.B., D.Sc. New Edition, revised. Crown 8vo. 6s.

A COURSE OF ELEMENTARY PRACTICAL PHYSIOLOGY. By Prof. MICHAEL FOSTER, M.D., Sec. R.S., &c., and J. N. LANGLEY, M.A., F.R.S., Fellow of Trinity College, Cambridge. Fifth Edition. Crown 8vo 7s. 6d.

AN INTRODUCTION TO THE OSTEOLOGY OF THE MAMMALIA. By WILLIAM HENRY FLOWER, LL.D., F.R.S., Director of the Natural History Departments of the British Museum, late Hunterian Professor of Comparative Anatomy and Physiology in the Royal College of Surgeons of England. With numerous Illustrations. Third Edition. Revised with the assistance of HANS GADOW, Ph.D., M.A., Lecturer on the Advanced Morphology of Vertebrates and Strickland Curator in Univ. of Camb. Cr. 8vo 10s. 6d.

AN ATLAS OF PRACTICAL ELEMENTARY BIOLOGY. By G. B. HOWES, Assistant Professor of Zoology, Normal School of Science and Royal School of Mines. With a Preface by THOMAS HENRY HUXLEY, F.R.S. Royal 4to. 14s.

A COURSE OF INSTRUCTION IN ZOOTOMY (VERTEBRATA). By T. JEFFREY PARKER, B.Sc. London, Professor of Biology in the University of Otago, New Zealand. With Illustrations. Crown 8vo. 8s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, M.A., F.L.S., Professor of Botany in the University of Glasgow, and SYDNEY H. VINES, M.A., D.Sc., F.R.S., Fellow and Lecturer, Christ's College, Cambridge. With a Preface by W. T. THISELTON DYER, M.A., C.M.G., F.R.S., F.L.S., Director of the Royal Gardens, Kew.

Part I.—PHANEROGAMÆ—PTERIDOPHYTA. Crown 8vo, 6s.

STRUCTURAL BOTANY, OR ORGANOGRAPHY ON THE BASIS OF MORPHOLOGY. To which are added the Principles of Taxonomy and Phytography, and a Glossary of Botanical Terms. By Professor ASA GRAY, LL.D. 8vo. 10s. 6d.

THE STUDENT'S FLORA OF THE BRITISH ISLANDS. By Sir J. D. HOOKER, K.C.S.I., C.B., M.D., F.R.S., D.C.L. Third Edition, revised. Globe 8vo. 10s. 6d.

FIRST BOOK OF INDIAN BOTANY. By DANIEL OLIVER, F.R.S., &c., Professor of Botany in University College, London, &c. With Illustrations. Extra fcap 8vo. 6s. 6d.

DOMESTIC BOTANY: An Exposition of the Structure and Classification of Plants, and their Uses for Food Clothing, Medicine, and Manufacturing Purposes. By JOHN SMITH, A.L.S., &c. With Illustrations. New Issue. Crown 8vo. 12s. 6d.

EUROPEAN BUTTERFLIES, A HANDBOOK OF. By W. F. DE VISMES KANE, M.A., M.R.I.A., Member of the Entomological Society of London, &c. With Copper Plate Illustrations. Crown 8vo. 10s. 6d.

A LIST OF EUROPEAN RHOPALOCERA, WITH THEIR VARIETIES AND PRINCIPAL SYNONYMS. Reprinted from the *Handbook of European Butterflies*. Crown 8vo 1s.

MEDICINE.

MICRO-ORGANISMS AND DISEASE. An Introduction into the Study of Specific Micro-Organisms. By E. KLEIN, M.D., F.R.S., Lecturer on General Anatomy and Physiology in the Medical School of St. Bartholomew's Hospital, London. With 121 Illustrations. Third Edition. Revised. Crown 8vo. 6s.

ANTHROPOLOGY.

ANTHROPOLOGY. An Introduction to the Study of Man and Civilisation. By E. B. TYLOR, D.C.L., F.R.S. With numerous Illustrations. Crown 8vo. 7s. 6d.

PHYSIOGRAPHY AND GEOLOGY.

PHYSIOGRAPHY. An Introduction to the Study of Nature. By THOMAS HENRY HUXLEY, F.R.S. With numerous Illustrations, and Coloured Plates. New and Cheaper Edition. Crown 8vo. 6s.

CLASS-BOOK OF GEOLOGY. By ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland, and Director of the Museum of Practical Geology, London, formerly Murchison Professor of Geology and Mineralogy in the University of Edinburgh, &c. With upwards of 200 New Illustrations. Crown 8vo. 10s. 6d.

AGRICULTURE.

AGRICULTURAL CHEMICAL ANALYSIS, A Handbook of. By PERCY FARADAY FRANKLAND, Ph.D., B.Sc., F.C.S., Associate of the Royal School of Mines, and Demonstrator of Practical and Agricultural Chemistry in the Normal School of Science and Royal School of Mines, South Kensington Museum. Founded upon *Leitfaden für die Agricultur-Chemische Analyse*, von Dr. F. KROCKER. Crown 8vo. 7s. 6d.

POLITICAL ECONOMY.

A MANUAL OF POLITICAL ECONOMY. By Right Hon. HENRY FAWCETT, F.R.S. Sixth Edition, revised, with a chapter on "State Socialism and the Nationalisation of the Land," and an Index. Crown 8vo 12s.

A BRIEF TEXT-BOOK OF POLITIC[illegible] ECONOMY. By FRANCIS A. WALKER, M.A., Ph.D., Author of "Money," "Money in its Relation to Trade," &c. Crown 8vo. 6s. 6d.

MORAL PHILOSOPHY AND LOGIC.

THE HISTORY OF ETHICS, OUTLINES OF, FOR ENGLISH READERS. By HENRY SIDGWICK, M.A., LL.D., Knightbridge Professor of Moral Philosophy in the University of Cambridge, Author of "The Methods of Ethics," "The Principles of Political Economy," &c. Crown 8vo 3s. 6d.

THE ELEMENTS OF THE PSYCHOLOGY OF COGNITION. By the Rev. ROBERT JARDINE, B.D., D.Sc. (Edin.), Ex-Principal of the General Assembly's College, Calcutta. Second Edition, revised and Improved. Crown 8vo. 6s. 6d.

STUDIES IN DEDUCTIVE LOGIC. By the late W. STANLEY JEVONS, LL.D., M.A., F.R.S. Second Edition. Crown 8vo. 6s.

ANCIENT GEOGRAPHY.

MANUAL OF ANCIENT GEOGRAPHY. Translated from the German of Dr. HEINRICH KIEPERT. Crown 8vo. 5s.

HISTORY.

SHORT HISTORY OF THE ENGLISH PEOPLE. By JOHN RICHARD GREEN, M.A., LL.D., late Honorary Fellow of Jesus College, Oxford. With Coloured Maps, Genealogical Tables, and Chronological Annals. Crown 8vo. 8s. 6d. 117th Thousand.

ANALYSIS OF ENGLISH HISTORY, based on Green's "Short History of the English People." By C. W. A. TAIT, M.A., Assistant Master, Clifton College. Crown 8vo 3s. 6d.

⁂ *Other Volumes to follow.*

MACMILLAN & CO., LONDON.

MESSRS. MACMILLAN & CO.'S SCIENCE CLASS-BOOKS.

ASTRONOMY.—POPULAR ASTRONOMY. By Sir G. B. AIRY, K.C.B., F.R.S., late Astronomer-Royal. With numerous Illustrations Fcap 8vo 4s 6d.

ASTRONOMY.—ELEMENTARY LESSONS IN ASTRONOMY. By J. NORMAN LOCKYER, F.R.S. New Edition. With numerous Illustrations. Fcap 8vo 5s 6d. (Questions on, 1s 6d)

PHYSIOLOGY.—ELEMENTARY LESSONS IN PHYSIOLOGY. By THOMAS HENRY HUXLEY, F.R.S. New Edition With numerous Illustrations. Fcap 8vo. 4s 6d. (Questions on, 1s. 6d)

ANATOMY.—LESSONS IN ELEMENTARY ANATOMY. By ST. GEORGE MIVART, F.R.S. With numerous Illustrations. Fcap 8vo. 6s 6d

CHEMISTRY.—LESSONS IN ELEMENTARY CHEMISTRY. By Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations. Fcap 8vo. 4s. 6d Problems adapted to the same, by Professor THORPE. With Key. 18mo 2s

OWEN'S COLLEGE JUNIOR COURSE OF PRACTICAL CHEMISTRY. By F. JONES. With Preface by Sir HENRY E. ROSCOE, F R.S. New Edition. With numerous Illustrations Fcap. 8vo. 2s. 6d.

QUESTIONS ON CHEMISTRY. A Series of Problems and Exercises in Inorganic and Organic Chemistry. By F. JONES, F R.S.E., F.C.S Fcap. 8vo. 3s.

CHEMICAL THEORY.—EXPERIMENTAL PROOFS OF CHEMICAL THEORY FOR BEGINNERS. By WILLIAM RAMSAY, Ph.D. Fcap 8vo 2s 6d.

PHYSICS.—LESSONS IN ELEMENTARY PHYSICS. By Professor BALFOUR STEWART, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d. (Questions on, 2s)

ELECTRICITY AND MAGNETISM.—ELECTRICITY AND MAGNETISM. By Professor SILVANUS THOMPSON. With numerous Illustrations Fcap 8vo. 4s. 6d.

ELECTRICITY AND MAGNETISM, ABSOLUTE MEASUREMENTS IN. By Professor ANDREW GRAY, M.A., F.R.S.E. Pott 8vo. 3s. 6d.

ELECTRIC LIGHT ARITHMETIC. By R. E. DAY, M.A. Pott 8vo. 2s.

HEAT AND ELECTRICITY.—A COLLECTION OF EXAMPLES ON HEAT AND ELECTRICITY. By H. H. TURNER, B A , Fellow of Trinity College, Cambridge. Crown 8vo. 2s. 6d.

UNITS AND PHYSICAL CONSTANTS. By J. D. EVERETT, M.A., D.C.L., F.R.S., F.R.S.E., Professor of Natural Philosophy, Queen's College, Belfast. Second Edition. Globe 8vo. 5s.

STEAM.—AN ELEMENTARY TREATISE ON STEAM. By J. PERRY, C.E., Professor of Engineering Imperial College of Engineering, Yedo. With Illustrations, Numerical Examples, and Exercises. Fcap 8vo. 4s. 6d.

SOUND.—ELEMENTARY LESSONS ON SOUND. By Dr. W. H. STONE. With Illustrations Fcap. 8vo. 3s 6d.

ELEMENTARY SCIENCE.—NUMERICAL TABLES AND CONSTANTS IN ELEMENTARY SCIENCE By SYDNEY LUPTON, M.A , F.C S., F.C I. Globe 8vo. 2s. 6d.

CHEMICAL ARITHMETIC.—CHEMICAL ARITHMETIC. With 1200 Examples. By the same Author. Second Edition. Globe 8vo. 4s. 6d.

NATURAL PHILOSOPHY.—NATURAL PHILOSOPHY FOR BEGINNERS. By I. TODHUNTER, M.A., F.R.S. Fcap. 8vo. Part I.—The Properties of Solid and Fluid Bodies. With Illustrations. 3s. 6d. Part II.—Sound, Light, and Heat. 3s. 6d.

PHYSICAL GEOGRAPHY.—ELEMENTARY LESSONS IN PHYSICAL GEOGRAPHY. By ARCHIBALD GEIKIE, F R.S With numerous Illustrations. Fcap 8vo 4s. 6d (Questions, 1s. 6d.)

FIELD GEOLOGY.—OUTLINES OF FIELD GEOLOGY. By the same Author. With numerous Illustrations. Crown 8vo. 3s 6d.

GEOGRAPHY.—CLASS-BOOK OF GEOGRAPHY. By C. B. CLARKE, M.A.. F.G.S., F.R.S. New Edition, with Eighteen Coloured Maps. Fcap 8vo. 3s.

AGRICULTURE.—ELEMENTARY LESSONS IN THE SCIENCE OF AGRICULTURAL PRACTICE. By Professor H. TANNER. Fcap 8vo. 3s. 6d

BOTANY.—LESSONS IN ELEMENTARY BOTANY. By Professor OLIVER, F.R.S. New Edition. With numerous Illustrations. Fcap 8vo. 4s 6d

GEOGRAPHY.—SHORT GEOGRAPHY OF THE BRITISH ISLANDS. By J. R. GREEN and ALICE S. GREEN. With Maps. Fcap 8vo 3s 6d

POLITICAL ECONOMY.—POLITICAL ECONOMY FOR BEGINNERS. By MRS. FAWCETT. New Edition. With Questions, &c. Fcap. 8vo. 2s. 6d.

ECONOMICS.—THE ECONOMICS OF INDUSTRY. By Professor A. MARSHALL and MARY P. MARSHALL Fcap. 8vo. 2s 6d.

LOGIC.—LESSONS IN LOGIC, INDUCTIVE AND DEDUCTIVE. By W. STANLEY JEVONS, LL.D., M.A., F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 3s. 6d.

A TEXT-BOOK OF DEDUCTIVE LOGIC FOR THE USE OF STUDENTS.—By P. K. RAY, D Sc. (Lond and Edin.), Professor of Logic and Philosophy, Dacca College. Second Edition. Globe 8vo. 4s. 6d.

UNIVERSITY COLLEGE, LONDON.

ELEMENTARY CHEMISTRY FOR WOMEN.

Assistant Professor, H. FORSTER MORLEY, M.A.

A Course of Forty Meetings for Theoretical and Practical Instruction in Elementary Chemistry, including the Subjects required by Candidates preparing for the Matriculation Examination of the University of London, will be given on WEDNESDAYS and FRIDAYS at 4 p.m. during the Second and Third Terms, beginning on WEDNESDAY, January 12. Fee £4 4s.

J. M. HORSBURGH, M.A., Secretary

UNIVERSITY COLLEGE, LONDON.

GEOLOGY AND MINERALOGY.

Prof BONNEY will commence a Course of about Sixty Lectures on GEOLOGY on Tuesday, January 11, at 12 Noon

Also a Course of about Twenty Lectures on the Economic Aspects of Geology (for Students of Engineering), on Friday, January 14, at 2 p.m.

Instruction is given at other times in Microscopic Petrology and Museum and Field Work. For further particulars apply to

J. M. HORSBURGH, M.A., Secretary.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

TWO ENTRANCE SCIENCE SCHOLARSHIPS of 125 Guineas and £60 respectively, open to all First-Year Students, will be offered for Competition in OCTOBER 1887

Special Classes are held throughout the Year for the "PRELIMINARY SCIENTIFIC" and "INTERMEDIATE M.B." Examinations of the University of London, and may be joined at any time.

Entries may be made to Lectures or to Hospital Practice, and special arrangements are made for Students entering in their Second or subsequent Years; also for Dental Students, and for Qualified Practitioners

Prospectuses and all particulars may be obtained from the Medical Secretary, Mr. George Rendle.

W. M. ORD, Dean.

WEYMOUTH COLLEGE.

Head Master . . . . Rev. JOHN MILLER, B.D.

The Distinctions gained direct from the School during the past year include:—

Tenth Place, India Civil Service; Third Place for Commissions in Royal Engineers; several Open Scholarships and Exhibitions at the Universities

In the July Examination of the Oxford and Cambridge Joint Boards, the only Distinctions gained in Biology and Botany were awarded to this School.

Fees, inclusive, from Sixty Guineas a year.

There will be an Examination for not less than three Entrance Scholarships, worth £40 a year, on Friday, January 21. For all particulars, apply to the Head Master

---

OWENS COLLEGE, MANCHESTER.

LENT TERM BEGINS on TUESDAY, January 11. New Students will be admitted on Monday and following days between 10.30 a.m. and 2.30 p.m.

H. W. HOLDER, M.A., Registrar.

BERKHAMPSTED SCHOOL, HERTS.

Twenty-eight miles from Euston. Good Scholarships and Exhibitions. Laboratory, heated swimming-bath, workshop, &c. £52 per annum.—Address, Head-Master.

UNIVERSITY CORRESPONDENCE

CLASSES.—Science Students, living in the country or in London, and wishing for assistance by correspondence or orally in any branch of Science, Elementary or Advanced, can obtain it from the Science Tutors of the University Correspondence Classes. Students can, if they desire it, be prepared for the B.Sc. of the London University. Very successful. Terms moderate.—Secretary, Mr E. S. Weymouth, M.A. (Lond.) Christchurch Road, Brondesbury, London, N.W.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to
THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers Actinosphaerium Eichhornii, with drawing and description. He also sent out Floscularia cornuta, Melicerta ringens, Stephanoceros Eichhornii, Diaptomus castor, Trout Ova, Desmids, Difflugia; also Hydra, Amoeba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1s per bottle, with full instructions for use, from most Opticians. Post free for 1s. 3d. from

EDWARD WARD, 249, Oxford Street, Manchester. [503

ROCKS, MINERALS, FOSSILS.

F. H. BUTLER,

Assoc. R. S. Mines Lond., M.A. Oxon., L.S.A. Lond., &c.,

Successor to the late R. TALLING,

180, BROMPTON ROAD, LONDON, S.W.

Just Received:—A large series of Palaeozoic and Mesozoic Fossils from a well-known collection, all in fine preservation; also a varied assortment of mounted Foraminifera, and of new or little known Cornish and Highland Rocks. Mineral Lists shortly ready.

SIX PRIZE MEDALS

AWARDED FOR GEOLOGICAL COLLECTIONS.

MEDICINE.

A TEXT-BOOK OF PHARMACOLOGY, THERAPEUTICS, AND MATERIA MEDICA. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.C.P., F.R.S., Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London, late Examiner in the University of Edinburgh. Adapted to the United States Pharmacopœia, by FRANCIS H. WILLIAMS, M.D., Boston, Mass. Second Edition. Adapted to the New British Pharmacopœia, 1885. Medium 8vo. 21s.

TABLES OF MATERIA MEDICA: a Companion to the Materia Medica Museum. By the same Author. With Illustrations. New Edition Enlarged. 8vo. 10s. 6d.

TEXT-BOOK OF PATHOLOGICAL ANATOMY AND PATHOGENESIS. By Prof. ERNST ZIEGLER of Tubingen. Translated and Edited for English Students by DONALD MACALISTER, M.A., M.D., B.Sc., F.R.C.P., Fellow and Medical Lecturer of St. John's College, Cambridge, Physician to Addenbrooke's Hospital, and Teacher of Medicine in the University. With numerous Illustrations. Medium 8vo.
Part I.—GENERAL PATHOLOGICAL ANATOMY. 12s. 6d.
Part II.—SPECIAL PATHOLOGICAL ANATOMY. Sections I.—VIII. 12s. 6d. Sections IX.—XII. 12s. 6d.

MICRO-ORGANISMS AND DISEASE. An Introduction into the Study of Specific Micro-Organisms. By E. KLEIN, M.D., F.R.S., Lecturer on General Anatomy and Physiology in the Medical School of St. Bartholomew's Hospital, London. With 121 Illustrations. Third Edition. Revised. Crown 8vo. 6s.

MACMILLAN & CO., LONDON.

MESSRS. MACMILLAN & CO.'S SCIENTIFIC WORKS.

NATURAL PHILOSOPHY.

A Text-Book of the Principles of Physics. By ALFRED DANIELL, M.A., LL.B., D.Sc., F.R.S.E., late Lecturer on Physics in the School of Medicine, Edinburgh. With Illustrations. Second Edition. Revised and Enlarged. Medium 8vo. 21s.

Elementary Practical Physics, Lessons in. By Professor BALFOUR STEWART, F.R.S., and W. W. HALDANE GEE, B.Sc. Crown 8vo.
Part I.—GENERAL PHYSICAL PROCESSES. 6s.
Part II.—ELECTRICITY AND MAGNETISM. [*In the press.*
Part III.—OPTICS, HEAT, AND SOUND. [*In preparation.*

A School Course of Practical Physics. By the same Authors. [*In preparation.*

Physics, Elementary Lessons in. By Professor BALFOUR STEWART, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo 4s 6d. (Questions on, 2s.)

Primer of Physics. By the same Author. With numerous Illustrations. New Edition, with Questions. 18mo. 1s. [*Science Primers.*

On Light. Being the Burnett Lectures, delivered in Aberdeen in 1883-1885. By GEORGE GABRIEL STOKES, M.A., P.R.S., &c., Fellow of Pembroke College, and Lucasian Professor of Mathematics in the University of Cambridge. First Course. ON THE NATURE OF LIGHT.—Second Course. ON LIGHT AS A MEANS OF INVESTIGATION. Crown 8vo. 2s. 6d. each.
THIRD COURSE. ON THE BENEFICIAL EFFECTS OF LIGHT. [*In the press.*

Spectrum Analysis. Lectures delivered in 1868 before the Society of Apothecaries of London. By Sir HENRY E. ROSCOE, LL.D., F.R.S., Professor of Chemistry in the Owens College, Victoria University, Manchester. Fourth Edition, revised and considerably enlarged by the Author and by ARTHUR SCHUSTER, F.R.S., Ph.D., Professor of Applied Mathematics in the Owens College, Victoria University. With Appendices, numerous Illustrations, and Plates. Medium 8vo. 21s.

Mechanical Theory of Heat. By R. Clausius. Translated by WALTER R. BROWNE, M.A., late Fellow of Trinity College, Cambridge. Crown 8vo. 10s. 6d.

Heat. By P. G. Tait, M.A., Sec. R.S.E., formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh. Crown 8vo. 6s.

Light: A Course of Experimental Optics, CHIEFLY WITH THE LANTERN. By LEWIS WRIGHT. With 200 Engravings and Coloured Plates. Crown 8vo. 7s. 6d.

Natural Philosophy for Beginners. By I. TODHUNTER, M.A., F.R.S. Fcap. 8vo. Part I.—The Properties of Solid and Fluid Bodies. With Illustrations. 3s. 6d. Part II.—Sound, Light, and Heat. 3s. 6d.

Electrostatics and Magnetism, Reprints of Papers on. By Sir WILLIAM THOMSON, D.C.L., LL.D., F.R.S., F.R.S.E., Fellow of St. Peter's College, Cambridge, and Professor of Natural Philosophy in the University of Glasgow. Second Edition. Medium 8vo. 18s.

Electricity and Magnetism. By Professor SILVANUS THOMPSON. With numerous Illustrations. Fcap. 8vo. 4s. 6d.

Electricity and Magnetism, Absolute Measurements in. By Professor ANDREW GRAY, M.A., F.R.S.E. Pott 8vo. 3s. 6d.

Electric Light Arithmetic. By R. E. Day, M.A. Pott 8vo. 2s.

Heat and Electricity, A Collection of Examples on. By H. H. TURNER, B.A., Fellow of Trinity College, Cambridge. Crown 8vo. 2s. 6d.

Steam, An Elementary Treatise on. By J. PERRY, C.E., Professor of Engineering in the Imperial College of Engineering, Yedo. With Illustrations, Numerical Examples, and Exercises. Fcap. 8vo. 4s 6d.

Sound, Elementary Lessons on. By Dr. W. H. STONE. With Illustrations. Fcap. 8vo. 3s. 6d.

Units and Physical Constants. By J. D. EVERETT, M.A., D.C.L., F.R.S., F.R.S.E., Professor of Natural Philosophy, Queen's College, Belfast. Second Edition. Globe 8vo. 5s.

Applied Mechanics: An Elementary General Introduction to the Theory of Structures and Machines. By JAMES H. COTTERILL, F.R.S., Associate Member of the Council of the Institution of Naval Architects, Associate Member of the Institution of Civil Engineers, Professor of Applied Mechanics in the Royal Naval College, Greenwich. Medium 8vo. 18s.

NATURAL PHILOSOPHY—*Continued.*

The Kinematics of Machinery. Outlines of a Theory of Machines. By Professor F. REULEAUX. Translated and Edited by Professor A. B. W. KENNEDY, C[illegible] With 450 Illustrations. Medium 8vo. 21s.

The Mechanics of Machinery. By Alex. B. W. KENNEDY, C.E., Professor of Civil and Mechanical Engineering in University College, London. With Illustrations. Crown 8vo 12s. 6d.

Elementary Science, Numerical Tables and CONSTANTS IN. By SYDNEY LUPTON, M.A., F.C.S., F.C.I. Globe 8vo. 2s. 6d.

Chemical Arithmetic. With 1200 Examples. By the same Author. Second Edition. Globe 8vo. 4s. 6d.

ASTRONOMY.

Popular Astronomy. By S. Newcomb, LL.D., Professor U.S. Naval Observatory. With 112 Illustrations and 5 Maps of the Stars. Second Edition, revised. 8vo. 18s.

Popular Astronomy. By Sir G. B. Airy, K.C.B., F.R.S., late Astronomer-Royal. With numerous Illustrations. Fcap. 8vo. 4s 6d.

Astronomy, Elementary Lessons in. By J. NORMAN LOCKYER, F.R.S. New Edition. With numerous Illustrations. Fcap 8vo 5s. 6d. (Questions on, 1s. 6d.)

The Chemistry of the Sun. By J. Norman LOCKYER, F.R.S. With Illustrations. Demy 8vo. 14s.

Primer of Astronomy. By J. Norman LOCKYER, F.R.S. With numerous Illustrations. New Edition. 18mo. 1s. [*Science Primers.*

CHEMISTRY.

Inorganic and Organic Chemistry. A Complete Treatise on Inorganic and Organic Chemistry. By Sir HENRY E. ROSCOE, F.R.S., and Professor C. SCHORLEMMER, F.R.S. With numerous Illustrations. Medium 8vo.
Vols. I. and II.—INORGANIC CHEMISTRY.
Vol. I.—The Non-Metallic Elements. 21s. Vol. II. Part I.—Metals. 18s. Vol. II. Part II.—Metals. 18s.
Vol III.—ORGANIC CHEMISTRY. Three Parts.
The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. With numerous Illustrations. Medium 8vo. Parts I. and II., 21s. each. Part III., 18s.

Elements of Chemical Physics. By Josiah P. COOKE, Junr., Erving Professor of Chemistry and Mineralogy in Harvard University. Fourth Edition. Royal 8vo. 21s.

A Manual of the Chemistry of the Carbon COMPOUNDS, OR ORGANIC CHEMISTRY. By C. SCHORLEMMER, F.R.S., Professor of Chemistry in the Victoria University, the Owens College, Manchester. With Illustrations. 8vo 14s.

The Elements of Thermal Chemistry. By M. M. PATTISON MUIR, M.A., F.R.S.E., Fellow and Prælector of Chemistry in Gonville and Caius College, Cambridge; Assisted by DAVID MUIR WILSON. 8vo. 12s. 6d.

The Study of Chemistry, an Introduction TO. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

Compounds of Carbon; or, Organic Chemistry, an Introduction to the Study of. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

Chemistry, Elementary Lessons in. By Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations. Fcap 8vo. 4s. 6d. Problems adapted to the same, by Professor THORPE. With Key. 18mo. 2s.

Owen's College Junior Course of Practical CHEMISTRY. By F. JONES. With Preface by Sir HENRY E. ROSCOE, F.R.S. New Edition With numerous Illustrations. Fcap. 8vo. 2s. 6d.

Questions on Chemistry. A Series of Problems and Exercises in Inorganic and Organic Chemistry. By F. JONES, F.R.S.E., F.C.S. Fcap. 8vo. 3s.

Primer of Chemistry. By Sir Henry E. ROSCOE, F.R.S. With numerous Illustrations. New Edition. With Questions. 18mo. 1s. [*Science Primers.*

Chemical Theory, Experimental Proofs of, FOR BEGINNERS. By WILLIAM RAMSAY, Ph.D. Fcap. 8vo. 2s. 6d.

MACMILLAN & CO., LONDON.

Printed by RICHARD CLAY AND SONS, at 7 and 8, Bread Street Hill, Queen Victoria Street, in the City of London, and Published by MACMILLAN AND CO. at the Office, 29 and 30 Bedford Street, Covent Garden.—THURSDAY, January 6, 1887

GOLD MEDAL,
International Inventions Exhibition, 1885.

Now Ready, Vol. VII., pp. 460, with 13 Plates, Price 21s.

THE JOURNAL OF PHYSIOLOGY.

Edited, with the Co-operation in England of
Prof. W. RUTHERFORD, F.R.S., of Edinburgh, Prof. J. BURDON-SANDERSON, F.R.S., of Oxford; and in America of Prof. H. P. BOWDITCH, of Boston; Prof. H. NEWELL MARTIN, F.R.S., of Baltimore; Prof H. C. WOOD, of Philadelphia,

BY
MICHAEL FOSTER, M.D., F.R.S.

THE CAMBRIDGE SCIENTIFIC INSTRUMENT COMPANY,
CAMBRIDGE.

WEYMOUTH COLLEGE.

Head Master . . . Rev. JOHN MILLER, B.D.

The Distinctions gained direct from the School during the past year include:—

Tenth Place, India Civil Service; Third Place for Commissions in Royal Engineers; several Open Scholarships and Exhibitions at the Universities

In the July Examination of the Oxford and Cambridge Joint Boards, the only Distinctions gained in Biology and Botany were awarded to this School.

Fees, inclusive, from Sixty Guineas a year.

There will be an Examination for not less than three Entrance Scholarships, worth £40 a year, on Friday, January 21. For all particulars, apply to the HEAD MASTER.

Just Published, Fifth Edition, Revised and Enlarged,

OUR EYES,
AND
HOW TO PRESERVE THEM,
FROM
INFANCY TO OLD AGE.
WITH SPECIAL INFORMATION ABOUT SPECTACLES.
BY JOHN BROWNING,
F.R.A.S., F.R.M.S., &c.
With 55 ILLUSTRATIONS. Price 1s. Cloth.

OUR EYES.

Extracts from Notices of the First Edition:—

"'How-to-Use Our Eyes,' by John Browning, F.R.A.S., is a thoroughly practical little manual."—*Graphic.*

"Gives many a useful hint to those who enjoy good eyesight and wish to preserve it, and gives the advice of an oculist to those obliged to wear spectacles."—*Pall Mall Gazette.*

ROYAL INSTITUTION OF GREAT BRITAIN.

ALBEMARLE STREET, PICCADILLY, W.

AFTERNOON LECTURES BEFORE EASTER, 1887.

LECTURE HOUR 3 o'clock p.m.

Prof. ARTHUR GAMGEE, M.D., F.R.S. Eleven Lectures on "The Function of Respiration." On Tuesdays, January 18 to March 29. One Guinea the Course.

Prof. A. W. RÜCKER, M.A., F.R.S., M.R.I. Five Lectures on "Molecular Forces." On Thursdays, January 20, 27, February 3, 10, 17. One Guinea.

EDMUND GOSSE, Esq., M.A., Clark Lecturer in English Literature, Trinity College, Cambridge. Three Lectures on "The Critics of the Age of Anne." On Thursdays, February 24, March 3, 10. Half-a-Guinea.

Prof. F. MAX MÜLLER, M.A., LL.D. Three Lectures on "The Science of Thought." On Thursdays, March 17, 24, 31. Half-a-Guinea.

CARL ARMBRUSTER, Esq. Five Lectures on "Modern Composers of Classical Song." On Saturdays, January 22, 29, February 5, 12, 19. One Guinea.

The RIGHT HON. LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.S., M.R.I. Six Lectures on "Sound." On Saturdays, February 26, March 5, 12, 19, 26, April 2. One Guinea.

Subscription (to Non-Members) to all the Courses during the Season, Two Guineas. Tickets issued daily at the Institution, or sent by Post on receipt of Cheque or Post-Office Order.

GUY'S HOSPITAL MEDICAL SCHOOL.

UNIVERSITY OF LONDON, PRELIMINARY SCIENTIFIC (M.B.) EXAMINATION.

Instruction is given in all the subjects of the above Examination at GUY'S HOSPITAL during the Winter and Summer Sessions. The Fee for the whole Course is 10 Guineas. The Class is not confined to Students of the Hospital.

For further particulars, apply to the DEAN, Guy's Hospital, Southwark, S.E.

BEDFORD COLLEGE, LONDON

(FOR LADIES),

8 AND 9, YORK PLACE, BAKER STREET, W.

LENT TERM will begin on Thursday, January 20, 1887. Lectures in BOTANY are given by Prof. BENNETT; Lectures in ZOOLOGY by W. B. BENHAM, B.Sc. Lond.

B. SHADWELL, Hon. Sec.

UNIVERSITY CORRESPONDENCE CLASSES.—Science Students, living in the country or in London, and wishing for assistance by correspondence or orally in any branch of Science, Elementary or Advanced, can obtain it from the Science Tutors of the University Correspondence Classes. Students can, if they desire it, be prepared for the B.Sc. of the London University. Very successful. Terms moderate.—Secretary, Mr. E. S. WEYMOUTH, M.A. (Lond.) Christchurch Road, Brondesbury, London, N.W.

A FRENCH GENTLEMAN, with First-rate Scholastic Recommendations, has a French Class for Army Pupils at 2, Colville Gardens, Bayswater. He and his wife also receive as Boarders two or three Young Men who wish to study the language for business or conversational purposes.—Address M. ALFRED VIGIER, Swanley, Kent.

BERKHAMPSTED SCHOOL, HERTS. Twenty-eight miles from Euston. Good Scholarships and Exhibitions. Laboratory, heated swimming-bath, workshop, &c. £52 per annum.—Address, Head-Master.

FATAL GAP in SCIENTIFIC LITERATURE.—Educated and intelligent men who profess a certain knowledge of current topics, will read the last new Journal—"THE EARTH"—with shame and confusion at the discovery of their absolute ignorance of the most elementary principles of Physical Science, and that what they do know they know all wrong.—29, Paternoster Row. 1d.

LATITUDES and LONGITUDES and SOLAR COURSES, together with a Coloured and Highly Finished MAP of the WORLD, both of them compiled on the only correct principle ever published or procurable. 2s. 6d. to EDITOR, Cosmos House, Balham, Surrey.

FOR SALE.—A TELESCOPE with 3-inch Object-Glass by THOMAS COOK the Elder, Equatorially Mounted, with all necessary Eye-pieces, &c., driven by Clockwork, a Sidereal Time-piece, besides a beautiful Stand for outdoor work. The property of an Amateur. Price for the whole £20, scarcely half of its original cost.—Apply to F. d'A., 45 Walham Grove.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to THOMAS BOLTON, 57, NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers the Ova of Trout, Salmo fontinalis, with drawing and description. He also sent out Volvox globator, Glass Larva, Entomostraca, Spongilla fluviatilis, Brachionus urceolaris, Desmids, Difflugia, also Hydra, Amoeba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s. or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1s. per bottle, with full instructions for use, from most Opticians. Post free for 1s. 3d. from

EDWARD WARD, 249, Oxford Street, Manchester. [503

Diary of Societies

London

THURSDAY, January 13

Royal Society, at 4.30.—Supplemental Note on Polacanthus foxii—describing the Dorsal and some Parts of the Endoskeleton imperfectly known in 1881. J. W. Hulke, F.R.S.—The Reputed Suicide of Scorpions · Prof. A. G. Bourne.—Supplementary Note on the Values of the Napierian Logarithms of 2, 3, 5, 7, and 10, and of the Modulus of Common Logarithms · Prof. J. C. Adams, F.R.S —On the Crimson Line of Phosphorescent Alumina · W. Crookes, F.R.S.

Mathematical Society, at 8.—Conjugate "Tucker" Circles: R. Tucker.

London Institution, at 6—Chemical Action, II Dr. C. Meymott Tidy.

FRIDAY, January 14.

Geometrical Association (A I.G.T), at 2.—The Teaching of Modern Geometry: Rev. G. Richardson.—The Modern Treatment of Maxima and Minima: Rev. J. J. Milne.—Geometry from an Artist's point of view: G. A Storey.

Royal Astronomical Society, at 8.

SUNDAY, January 16.

Sunday Lecture Society, at 4.—The Unity of Structure in the Human Body—an Essay in Anatomy" (with oxy-hydrogen lantern illustrations): Ernest A. Parkyn, M.A.Cantab.

MONDAY, January 17.

Royal Geographical Society, at 8 30.

London Institution, at 5.—Fins, Wings, and Hands. Prof. W. H. Flower, F.R.S.

Victoria Institute, at 8.—New Assyrian Discoveries: W. St. C. Boscawen, F.R.Hist.Soc.

TUESDAY, January 18

Zoological Society, at 8.30—On the Fin of Ceratodus: G. B Howes, F.Z S.—Notes on Carcharodon rondeletii: Prof T. Jeffery Parker, C.M Z.S.—On some Foraminifera from the Abrohlos Bank. Messrs. H. B. Brady, F.R.S , W. Kitchen Parker, F R.S., and T. Rupert Jones, F.R.S.

Royal Institution, at 3—The Function of Respiration: Prof Arthur Gamgee, M.D., F.R.S.

Middlesex Natural History and Science Society, at 8.—On the Water in the Chalk beneath the London Clay in the London Basin: R. B Hayward, F.R.S.

Institution of Civil Engineers, at 8.—The Use and Equipment of Engineering Laboratories: Prof. Alex. B. W. Kennedy. (Discussion.)

WEDNESDAY, January 19.

Royal Meteorological Society, at 7.—On the Identity of Cloud Forms all over the World, and on the General Principles by which their Indications must be read, and On the Cloud to which the name "Roll-Cumulus" has been applied: Hon Ralph Abercromby.—Annual General Meeting, at 8.

Entomological Society, at 7—Anniversary.

THURSDAY, January 20.

Royal Society, at 4 30

Linnean Society, at 8—Stimulation on Turgescent Vegetable Tissues: F. Darwin and A. Bateson—Hydroids and Polyzoa of Mergui Archipelago: Rev T. Hincks.—Tissues of Sporophore in Mosses: J. R. Vaizey.

Chemical Society, at 8—Some New Silicon Compounds and their Derivatives—I. The Action of Silicon Tetrabromide on Thio-carbamide: J. Emerson Reynolds, F.R.S.—Derivatives of Chromo-organic Acids—I. Certain Chromo-oxalates: Emil A. Werner.—Remarks on Baeyer's Paper "On the Constitution of Benzene: Dr. A. K. Miller.

Royal Institution, at 3.—Molecular Forces: Prof. A. W. Rücker, M.A., F.R S.

London Institution, at 6.—Chemical Action, III.: Dr. C. Meymott Tidy.

FRIDAY, January 21.

Royal Institution, at 9.—The Probable Origin, the Total Amount, and the Possible Duration of the Sun's Heat: Sir William Thomson, F.R.S.

Institution of Civil Engineers, at 7.30.—The Use of Cast Steel in Locomotive Construction: Alfred J. Hill.

WATSON & SONS' NEW HISTOLOGICAL MICROSCOPE,

AWARDED GOLD MEDAL, LIVERPOOL EXHIBITION, 1886.

FREE ON APPLICATION.

ILLUSTRATED CATALOGUE
OF
MICROSCOPES
AND
APPARATUS.

Classified List of 40,000 First-class Microscopic Objects.

A thoroughly first-rate Microscope at an extremely moderate price. It is mounted on an exceedingly firm brass foot, has sliding body for coarse adjustment, draw-tube, plane and concave mirrors, tube fitting of universal size for under-stage apparatus, with special arrangement for oblique illumination, set of diaphragms, with pin-hole stop, and is fitted with WATSON & SON'S improved form of fine adjustment, as supplied to their best instruments, which is perfectly free from all lateral motion, even when working with the highest powers, and permits of the greatest possible delicacy of adjustment. The entire instrument is finished in the very best manner, and is unequalled in value at the price.

Microscope as illustrated, with "C" eye-piece, ¼ and 1 inch first-class English objectives, giving a range of amplification from 75 to 700 diameters, in mahogany cabinet, price

£4 15s. 0d.

W. WATSON & SONS, Opticians to H.M. Government,
313 HIGH HOLBORN, LONDON, W.C. ESTABLISHED 1837.

ELECTRICAL ENGINEERING.

CITY AND GUILDS OF LONDON INSTITUTE.

The Courses of Technical Instruction at the Central Institution, Exhibition Road, S.W., are open to persons desirous of studying any branch of ELECTRICAL ENGINEERING. The Instruction, under the general direction of Prof. AYRTON, F.R.S., comprises Lectures and Practice in the Laboratories and Dynamo-Room. For particulars apply at Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

DYNAMO-ELECTRIC MACHINERY.

A Special Course of PRACTICAL DEMONSTRATIONS in the TESTING of the POWER and EFFICIENCY of DYNAMOS and MOTORS will be given by Prof. AYRTON, F.R.S., at the CENTRAL INSTITUTION of the CITY and GUILDS of LONDON INSTITUTE, commencing on FRIDAY, February 4, at 5 p.m. Fee for the Course £1 11s. 6d., or to Registered Teachers of the Institute 15s. For particulars apply at Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

CHEMISTRY OF THE ALKALOIDS, ETC.

CITY AND GUILDS OF LONDON INSTITUTE.

Prof. ARMSTRONG, F.R.S., will commence a Course of about Twenty Lectures on MONDAY NEXT, January 24, 1887, at the CENTRAL INSTITUTION, Exhibition Road, S.W., on the CHEMISTRY of NITROGEN and its COMPOUNDS, with Special Reference to Recent Investigations of the ALKALOIDS, ALBUMENOIDS, &c. The Lectures will be given at 5 p.m. on MONDAYS and WEDNESDAYS. Fee for the Course, £1 1s.

PHILIP MAGNUS, Director and Secretary.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

TWO ENTRANCE SCIENCE SCHOLARSHIPS of 125 Guineas and £60 respectively, open to all First-Year Students, will be offered for Competition in OCTOBER 1887.

Special Classes are held throughout the Year for the "PRELIMINARY SCIENTIFIC" and "INTERMEDIATE M.B." Examinations of the University of London, and may be joined at any time.

Entries may be made to Lectures or to Hospital Practice, and special arrangements are made for Students entering in their Second or subsequent Years; also for Dental Students, and for Qualified Practitioners.

Prospectuses and all particulars may be obtained from the Medical Secretary, Mr. GEORGE RENDLE. W. M. ORD, Dean.

GUY'S HOSPITAL MEDICAL SCHOOL.

UNIVERSITY OF LONDON, PRELIMINARY SCIENTIFIC (M.B.) EXAMINATION.

Instruction is given in all the subjects of the above Examination at GUY'S HOSPITAL during the Winter and Summer Sessions. The Fee for the whole Course is 10 Guineas. The Class is not confined to Students of the Hospital.

For further particulars, apply to the DEAN, Guy's Hospital, Southwark, S.E.

A FRENCH GENTLEMAN, with First-rate Scholastic Recommendations, has a French Class for Army Pupils at 2, Colville Gardens, Bayswater. He and his wife also receive as Boarders two or *three Young Men who* wish to study the language for business or conversational purposes.—Address M. ALFRED VIGUER, Swanley, Kent.

BERKHAMPSTED SCHOOL, HERTS.

Twenty-eight miles from Euston. Good Scholarships and Exhibitions. Laboratory, heated swimming-bath, workshop, &c. £52 per annum.—Address, Head-Master.

UNIVERSITY CORRESPONDENCE CLASSES.—Science Students, living in the country or in London, and wishing for assistance by correspondence or orally in any branch of Science, Elementary or Advanced, can obtain it from the Science Tutors of the University Correspondence Classes. Students can, if they desire it, be prepared for the B.Sc. of the London University. Very successful. Terms moderate.—Secretary, Mr. E. S. WEYMOUTH, M.A. (Lond.), Christchurch Road, Brondesbury, London, N.W.

MARVELLOUS MEMORY DISCOVERY

(UNLIKE MNEMONICS),
And Cure of Mind Wandering.

Any Book Learned in One Reading. *Great Inducements to Correspondence Classes.*

New Prospectus from Prof. LOISETTE, 37, New Oxford Street, London.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to
THOMAS BOLTON, 57 NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers Coryne pusilla, with drawing and description. He also sent out Clava squamata, Trout Ova and Fry, Volvox *globator*, Brachionus pala, Triarthra longiseta, Glass Larva, Entomostraca, Desmids, Difflugia; also Hydra, Amoeba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s. or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

"BROWN CEMENT."

The name of this Cement, admitted *to* be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by *fraudulent* imitations.

Price 1s. per bottle, with full instructions for use, from most Opticians. Post free for 1s. 3d. from

EDWARD WARD, 245, Oxford Street, Manchester. [503

BRAIN:

A JOURNAL OF NEUROLOGY.

EDITORIAL COMMITTEE:

J. C. BUCKNILL, M.D., F.R.S., THOMAS BUZZARD, M.D., F.R.C.P., SIR J. CRICHTON-BROWNE, M.D., F.R.S., DAVID FERRIER, M.D., F.R.S., J. HUGHLINGS-JACKSON, M.D., F.R.S., and JAMES ROSS, M.D., F.R.C.P.

ACTING EDITOR:

A. DE WATTEVILLE, M.A., M.D., B.Sc.

Contents.

ORIGINAL ARTICLES—

Rotation of the Great Brain. By Alex. Hill, M.A., M.D.

Some of the Relationships between Epilepsy and Insanity. By C. H. Savage, M.D., F.R.C.P.

On Pseudo-Tabes from Arsenical Poisoning, with a Consideration of the Pathology of Arsenical Paralysis. By Charles L. Dana, A.M., M.D., New York.

Coma. By Charles Mercier, M.B.

A Contribution to the Pathology of Dreams and of Hysterical Paralysis. By Ch. Féré, M.D.

On Changes in Nervous System after Amputation of Limbs, with Bibliography and Recent Case. By Ernest S. Reynolds, M.D. (London).

Cases of Injury to the Cervical Region of the Spinal Cord. By William Thorburn, M.D., B.S. (Lond.), F.R.C.S.

Sequel to a "Case of Ophthalmoplegia, complicated with various other Affections of the Nervous System." By J. S. Bristowe, M.D., F.R.S.

CLINICAL CASES—

A Case of Hystero-Epileptoid Attacks, with Convulsions produced by Local Irritation of the Skin. By G. Parker, M.D.

A Case illustrating the Differential Diagnosis of Tumour of the Cord and Tumour of the Cauda Equina. By James Oliver, M.B., F.R.S. (Edin.).

ABSTRACTS OF BRITISH AND FOREIGN JOURNALS—

Wundt's Philosophische Studien. By J. McCattell, Ph.D.

Abstracts of Papers on Nervous Diseases published in St. Thomas's Hospital Reports from 1885 to 1884 (Vols. VI. to XIV. inclusive). By W. B. Hadden, M.D. (Lond.).

Westphal on a Peculiar Group of Symptoms—Rumpf on Syphilis, Infantile Paralysis, and Cerebellar Atrophy—Schulz on Aphasia, Hemianopsia, Spinal Sarcoma, and Tetanus. By W. J. Dodds, M.D., D.Sc.

Frew: a Report of a slight Outbreak of Epidemic Cerebrospinal Meningitis, with Notes of Six Cases—Middleton on the Pathology of Pseudo-hypertrophic Muscular Paralysis, with Remarks on a so-called Degeneration of the Nervous System—Beevor on Three Cases illustrating the Localisation of Motor Centres in the Brachial Enlargement of the Spinal Cord—Vost on a Case of Tubercular Tumour of the Cerebellum. By J. A. Ormerod, M.D.

Remak on a Case of Bilateral Paralysis of the Spinal Accessory Nerve—Hughes Bennett on Locomotor Ataxy, without Disease of the Posterior Columns of the Spinal Cord, and on a Case of Cerebral Tumour, the Surgical Treatment by Rickman J. Godlee. By J. F. Pringle, M.D.

MACMILLAN & CO., LONDON

BEST BLACK INK KNOWN.

DRAPER'S INK (DICHROIC).

DIFFERING FROM ANYTHING ELSE EVER PRODUCED.

Writing becomes a pleasure when this Ink is used. It has been adopted by the principal Banks, Public Offices, and Railway Companies throughout Ireland.

It writes almost instantly full Black.
Does not corrode Steel Pens.
Is cleanly to use, and not liable to Blot.

Flows easily from the Pen.
Blotting-paper may be applied at the moment of writing.

Can be obtained in London, through Messrs. BARCLAY & SONS, Farringdon Street; W. EDWARDS, Old Change; F. NEWBERY & SONS, Newgate Street; and to be had of all Stationers.

BEWLEY & DRAPER (Limited), Dublin.

In Crown 8vo, pp 560, price 10s 6d.

ALGEBRA:

An Elementary Text-Book

FOR THE

Higher Classes of Secondary Schools and for Colleges.

PART I.

BY GEO. CHRYSTAL, M.A.,

Late Fellow and Lecturer, Corpus Christi College, Cambridge, and Professor of Mathematics in the University of Edinburgh.

Edinburgh: ADAM & CHARLES BLACK.

Crown 8vo, Cloth, 7s. 6d.

PROPERTIES OF MATTER.

By P. G. TAIT, M.A., Sec. R.S.E.,

Formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh.

CONTENTS.—Introductory.—Some Hypotheses as to the Ultimate Structure of Matter.—Examples of Terms in Common Use as Applied to Matter.—Time and Space.—Impenetrability, Porosity, Divisibility.—Inertia, Mobility, Centrifugal Force.—Gravitation.—Preliminary to Deformability and Elasticity.—Compressibility of Gases and Vapours.—Compression of Liquids.—Compressibility and Rigidity of Solids.—Cohesion and Capillarity.—Diffusion, Osmose, Transpiration, Viscosity, &c.—Aggregation of Particles.

By the SAME. Crown 8vo, Price 6s.

LIGHT.

Edinburgh: ADAM & CHARLES BLACK.

Just Published.

Demy 8vo, cloth, pp. 400, Coloured Maps, Price 15s.

THE FLORA OF LEICESTERSHIRE,

INCLUDING THE CRYPTOGAMS. Compiled for the Leicester Literary and Philosophical Society by F. T. MOTT, F.R.G.S., E. T. COOPER, F.L.S., THOS. CARTER, LL.B., J. E. M. FINCH, M.D., and C. W. COOPER, M.B.

WILLIAMS & NORGATE, 14 Henrietta Street, Covent Garden, London; and Edinburgh.

FATAL GAP in SCIENTIFIC LITERATURE.—Educated and intelligent men, who profess a certain knowledge of current topics, will read the last new Journal—"THE EARTH"—with shame and confusion at the discovery of their absolute ignorance of the most elementary principles of Physical Science, and that what they do know they know all wrong.—29, Paternoster Row. 1d.

LATITUDES and LONGITUDES and SOLAR COURSES, together with a Coloured and Highly Finished MAP of the WORLD, both of them compiled on the only correct principle ever published or procurable. 2s. 6d. to EDITOR, Cosmos House, Balham, Surrey.

W. P. COLLINS, SCIENCE BOOKSELLER.—Secondhand and New. Specialty, Microscopy and Natural History. Catalogue and Monthly List free for Two Stamps. Libraries and Parcels of Books purchased or taken in exchange.—157 Great Portland Street, Oxford Street, London, W.

BOOKS (Secondhand), Miscellaneous, Remainders, &c.—C. HERBERT, English and Foreign Bookseller, 319 Goswell Road, London, E.C. Catalogue free on receipt of two stamps. Libraries, Old Books, and Parchments purchased.

Crown 8vo, pp 200, 2s 6d.

OUR MORALITY AND THE MORAL QUESTION.

By LIONEL BEALE, F.R.S., Professor of Medicine in King's College, London.

J. & A. CHURCHILL

On the 1st of every Month.

GEORGE BELL AND SONS' BOOKS.

CAMBRIDGE MATHEMATICAL SERIES. IN CROWN 8vo.

To those recently added an asterisk is prefixed.

*ARITHMETIC. By C. PENDLEBURY, M.A., F.R.A.S., Senior Mathematical Master of St. Paul's School. 4s. 6d.

ALGEBRA.—Choice and Chance. An Elementary Treatise on Permutations, Combinations, and Probability, with 640 Exercises. By W. A. WHITWORTH, M.A. Fellow of St. John's College, Cambridge. Fourth Edition, Revised and Enlarged. 6s.

*EUCLID.—Books I.-VI., and Part of Books XI. and XII., Newly Translated from the Greek Text, with Supplementary Propositions, Chapters on Modern Geometry, and numerous Exercises. By HORACE DEIGHTON, M.A., Head Master of Harrison College, Barbadoes. 4s. 6d.

EUCLID.—Exercises on Euclid and in Modern Geometry, containing Applications of the Principles and Processes of Modern Pure Geometry. By J. McDOWELL, M.A., F.R.A.S. Third Edition, Revised. 6s.

TRIGONOMETRY, Introduction to Plane. By the Rev. T. G. VYVYAN, M.A., Mathematical Master of Charterhouse. Third Edition, Revised and Augmented. 3s. 6d.

CONICS, the Elementary Geometry of. By C. TAYLOR, D.D., Master of St. John's College, Vice-Chancellor at Cambridge University. Fourth Edition, Revised and Enlarged. 4s. 6d.

CONIC SECTIONS. An Elementary Treatise. By H. G. WILLIS, M.A., Clare College, Cambridge, Assistant Master of Manchester Grammar School. 7s. 6d.

SOLID GEOMETRY, an Elementary Treatise on. By W. STEADMAN ALDIS, M.A., Trinity College, Cambridge, Professor of Mathematics in the University College, Auckland, N.Z. Third Edition, Revised. 6s.

*GEOMETRICAL OPTICS, an Elementary Treatise on. By W. S. ALDIS, M.A. Second Edition, Revised. 4s.

RIGID DYNAMICS, an Introductory Treatise on. By W. STEADMAN ALDIS, M.A. 4s.

ELEMENTARY DYNAMICS for the Use of Colleges and Schools. By WILLIAM GARNETT, M.A., Principal of the College of Physical Science, Newcastle-upon-Tyne. 4th Edition, Revised. 6s.

DYNAMICS, a Treatise on. By W. H. BESANT, D.Sc., F.R.S. 7s. 6d.

HEAT, an Elementary Treatise on. By WILLIAM GARNETT, M.A. Fourth Edition, Revised and Enlarged. 3s. 6d. [*In the press.*

HYDROMECHANICS, a Treatise on. By W. H. BESANT, D.Sc., F.R.S. Fourth Edition, Revised and Enlarged. Part I. Hydrostatics. 5s.

MECHANICS, a Collection of Problems in Elementary. By W. WALTON, M.A. Second Edition, Revised. 6s.

A NEW TEXT-BOOK OF GEOLOGY.

THE STUDENT'S HAND-BOOK of HISTORICAL GEOLOGY. By A. J. JUKES-BROWNE, B.A., F.G.S., of the Geological Survey of England and Wales. With numerous Diagrams and Illustrations. Small Post 8vo, 6s. Uniform in size and price with the same Author's "Physical Geology."

"Here, and generally, the book is well up to date. . . . Will prove a most useful book."—*Prof. A. H. Green in* NATURE.

"A thoroughly good practical text-book."—*Scotsman.*

"It is long since we came across so comprehensive a work, so well arranged, and so sensibly illustrated."—*Schoolmaster.*

BOTANY.

THE BOTANIST'S POCKET-BOOK. Containing in a tabulated form the Chief Characteristics of British Plants, with the Botanical Names, Soil or Situation, Colour, Growth, and Time of Flowering of every Plant, arranged under its own Order, with a Copious Index. By W. R. HAYWARD. Fifth Edition, with new Appendix. Crown 8vo, limp cloth, 4s. 6d.

CHEMISTRY.

EXPERIMENTAL CHEMISTRY, founded on the work of Dr. J. A. STÖCKHARDT. A Hand-book for the Study of the Science by Simple Experiments. New Edition, Revised. By C. W. HEATON, F.I.C., F.C.S., Lecturer on Chemistry in the Medical School of Charing Cross Hospital. Small Post 8vo, 5s.

TECHNOLOGICAL HAND-BOOKS.

Edited by H. TRUEMAN WOOD, B.A., Secretary to the Society of Arts.

A Series of Technical Manuals specially adapted for Candidates in the Examinations of the City Guilds Institute. In Small Post 8vo.

DYEING AND TISSUE-PRINTING. By WILLIAM CROOKES, F.R.S., V.P.C.S. 5s.

GLASS MANUFACTURE. Introductory ESSAY, by H. POWELL, B.A. (Whitefriars Glass Works); SHEET GLASS, by HENRY CHANCE, M.A. (Chance Bros., Birmingham); PLATE GLASS, by H. G. HARRIS, Assoc. Memb. Inst. C.E. 3s. 6d.

COTTON MANUFACTURE: its Development, PRINCIPLES, and PRACTICE, with Appendix on Steam Boilers and Engines. By R. MARSDEN, Editor of the *Textile Manufacturer.* Second Edition, Revised. 6s. 6d.

COAL-TAR COLOURS, the CHEMISTRY OF. With Special Reference to their Application to Dyeing, &c. By Dr. R. BENEDIKT, Professor of Chemistry in the University of Vienna. Translated from the German by E. KNECHT, Ph.D., Head Master of the Chemistry and Dyeing Department in the Technical College, Bradford. 5s.

Others preparing.

London: GEORGE BELL & SONS, York Street, Covent Garden.

NEW WORK BY PROFESSOR MILNES MARSHALL.

Ready This Day, with Numerous Illustrations, Crown 8vo, 10s. 6d.

A JUNIOR COURSE OF PRACTICAL ZOOLOGY.

By A. MILNES MARSHALL, M.D., D.Sc., M.A., F.R.S.,

Professor in the Victoria University; Beyer Professor of Zoology in Owens College; late Fellow of St. John's College, Cambridge.

Assisted by C. HERBERT HURST, Demonstrator and Assistant Lecturer in Zoology, Owens College, Manchester.

London: SMITH, ELDER, & CO., 15, Waterloo Place.

Sold by all the Leading Opticians in the United Kingdom, through whom please order.

YORK & SON,
87, Lancaster Road, Notting Hill, London, W.

FRY'S PURE

CONCENTRATED SOLUBLE **COCOA**

Prepared by a new and special scientific process Securing extreme solubility, and developing the finest flavour of the Cocoa.

HOLLOWAY'S PILLS THIS MEDICINE

Is a Certain Cure for all Disorders of the LIVER, STOMACH AND BOWELS. A Great PURIFIER of the BLOOD; a Powerful Invigorator of the System, in cases of WEAKNESS AND DEBILITY, and is unequalled in Female Complaints.

Popular Edition. One Shilling Each.

ENGLISH MEN OF LETTERS.

Edited by JOHN MORLEY.

The Publishers feel that the time has come when this series of Popular Biographies (upwards of 300,000 copies have been sold in their original form) may well be re-issued at a lower price for the benefit of a yet wider public than they have hitherto reached.

They have therefore decided to publish them in Monthly Volumes at One Shilling each in paper covers, or in limp cloth binding at Eighteenpence.

The original order of publication will be followed. And accordingly the first volumes to be issued are as under:—

JOHNSON. By LESLIE STEPHEN. [*Ready.*
SCOTT. By R. H. HUTTON. [*February.*
GIBBON. By J. COTTER MORISON. [*March*
SHELLEY. By J. A. SYMONDS. [*April.*

MACMILLAN & CO., LONDON.

GEOGRAPHY.

JOHNSTON.—Physical, Historical, Political, and Descriptive Geography. By Keith Johnston, F.R.G.S., Editor of "Stanford's Compendium of Geography and Travel in Africa." Third Edition. Revised by E. G. Ravenstein, F.R.G.S. With numerous Maps and Illustrations. Large post 8vo 12s.

JOHNSTON.—A School Physical and Descriptive Geography. By Keith Johnston, F.R.G.S. Third Edition. Revised by E. G. Ravenstein, F.R.G.S. With Maps and Illustrations. Crown 8vo, cloth, 6s.

JOHNSTON.—An Intermediate Physical and Descriptive Geography. Abridged from the Physical, Historical, and Descriptive Geography by the late Keith Johnston, F.R.G.S. With several Illustrations. Crown 8vo, cloth, 3s. Revised and Corrected to date, and intended for use in schools where the two larger works by the same Author are not found suitable.

ZIMMERN.—Geography for Little Children. By Antonia Zimmern. With Forty Maps and Illustrations. Second Edition. Post 8vo, cloth, 1s.

SCHOOL ATLASES.

STANFORD'S LONDON ATLAS of UNIVERSAL GEOGRAPHY. Quarto Edition. Containing Forty-four coloured Maps, carefully drawn and beautifully engraved on steel and copper plates, and an Alphabetical Index to the Geography of the World. Second Edition. Half morocco, cloth sides, gilt edges, 30s. Size when shut, 15 in. by 12½ in.

STANFORD'S INTERMEDIATE SCHOOL PHYSICAL and POLITICAL ATLAS. A Series of Forty-three Coloured Maps, comprising Physical and Political Maps of the great Continents and their Divisions, also the World in Hemispheres, and Charts of Ocean Currents and Prevailing Winds. Crown 4to, cloth, 4s.

INSTRUCTIVE ATLAS of MODERN GEOGRAPHY; containing Seventeen Coloured Maps each 17 in. by 14 in. Uniform in size and price with the "Instructive Picture Books." Fcap. folio, 7s. 6d.

ELEMENTARY PHYSICAL ATLAS, intended chiefly for Map Drawing and the Study of the great Physical Features and Relief Contours of the Continents, with an Introduction to serve as a Guide for both purposes. By the Rev. J. P. Faunthorpe, M.A., F.R.G.S., Principal of Whitelands Training College. Tenth Edition. Sixteen Coloured Maps, with Descriptive Letterpress, containing Hints on Map Drawing, &c. Price 4s.

By the same Author

OUTLINE ATLAS. Containing Sixteen Maps. Coloured wrapper, 1s.

PROJECTION ATLAS. Containing Sixteen Plates of Projections. Coloured wrapper, 1s.

BLANK SHEETS for MAPS. Sixteen Leaves of Blank Paper for Map Drawing. Coloured wrapper, 6d.

GEOLOGY.

RAMSAY.—Physical Geology and Geography of Great Britain. By Sir Andrew C. Ramsay, LL.D., F.R.S., &c., late Director-General of the Geological Survey. Fifth Edition. Considerably enlarged and Illustrated with numerous Sections and a Geological Map of Great Britain, printed in Colours. Post 8vo, cloth, 15s.

GEIKIE.—Outlines of Geology: an Introduction to the Science for Junior Students and General Readers. By James Geikie, LL.D., F.R.S., Murchison Professor of Geology and Mineralogy in the University of Edinburgh, formerly of H.M. Geological Survey; Author of "The Great Ice Age," "Prehistoric Europe," &c. With 400 Illustrations. Large post 8vo, 12s.

BARNES.—Rock History: a Concise Note-book of Geology, having Special Reference to the English and Welsh Formations. By C. L. Barnes, M.A., late Scholar of Balliol College, Oxford, Science Master at Bromsgrove School. With Coloured Maps of Strata, and Illustrations of Fossils. Crown 8vo, cloth, 6s.

SHARP.—Rudiments of Geology. By the late Samuel Sharp, F.S.A., F.G.S. Introductory and Physical, Stratigraphical and Palæontological. Second Edition, Revised and Enlarged. Crown 8vo, cloth, 4s.

BOTANY.

HENSLOW.—Botany for Children. An Illustrated Elementary Text-book for Junior Classes and Young Children. Numerous Plates and Descriptive Letterpress. By Rev. George Henslow, M.A., F.L.S., F.G.S., Author of "Floral Dissections," &c. Third Edition. Crown 8vo, cloth, 4s.

Coloured Edition, with the Plates coloured by hand. Crown 8vo, cloth, gilt edges, &c., 14s.

HENSLOW.—Floral Dissections. Illustrative of Typical Genera of the British Natural Orders. Lithographed by the Rev. George Henslow, M.A., F.L.S., F.G.S. For the Use of Schools and Students in Botany. Eight Plates. With Descriptive Letterpress. Demy 4to, stiff boards, cloth back, 4s.

BUCKLEY.—Botanical Tables for the Use of Junior Students. Table of Common Terms used in Describing Plants, comprising those usually required in the Cambridge Local Examinations for Juniors. Also a Table of the Chief Natural Orders of British Plants, arranged according to Bentham and Oliver. New and Revised Edition. By Arabella B. Buckley. Folded in cloth cover, 1s. 6d.

CHEMISTRY.

GILL.—Chemistry for Schools. An Introduction to the Practical Study of Chemistry. By C. Haughton Gill, late Assistant Examiner in Chemistry at the University of London. Seventh Edition. One Hundred Illustrations. Crown 8vo, cloth, 4s. 6d.

BARFF.—Elementary Chemistry. By F. S. Barff, M.A., Professor of Chemistry at the Royal Academy of Arts. Illustrated with Diagrams, and containing Questions for Calculation, and a Special Chapter on Apparatus. Fcap. 8vo, cloth, 1s. 6d.

MORGAN.—Water and its Teachings in Chemistry, Physics, and Physiography. A Suggestive Hand-book. By C. Lloyd Morgan, F.G.S., Associate of the Royal School of Mines, &c. 18mo, cloth, 2s. 6d.

MORGAN.—Facts Around Us. Simple Readings in Inorganic Science, with Experiments. By C. Lloyd Morgan, F.G.S., Associate of the Royal School of Mines, &c., Author of "Water and its Teachings." 18mo, cloth, [illegible] 6d.

SCIENCE.

BUCKLEY.—The Fairy-land of Science. By Arabella B. Buckley, Author of "Life and Her Children," &c. Nineteenth Thousand. With Seventy-four Illustrations. Crown 8vo, cloth gilt, gilt edges, 6s.

BUCKLEY.—Life and Her Children. Glimpses of Animal Life from the Amœba to the Insects. By Arabella B. Buckley, Author of "The Fairy-land of Science," &c. Eleventh Thousand. With upwards of One Hundred Illustrations. Crown 8vo, cloth gilt, gilt edges, 6s.

BUCKLEY.—Winners in Life's Race; or, the Great Backboned Family. By Arabella B. Buckley, Author of "The Fairy-land of Science," "Life and Her Children," &c. With numerous Illustrations. Fourth Thousand. Crown 8vo, cloth gilt, gilt edges, 8s. 6d.

BUCKLEY.—A Short History of Natural Science, and of the Progress of Discovery from the Time of the Greeks to the Present Day. For the Use of Schools and Young Persons. By Arabella B. Buckley. Third Edition. With Seventy-seven Illustrations. Crown 8vo, cloth, 7s. 6d.; gilt edges and Illustrated cover, 8s. 6d.

INFANT-SCHOOL MANAGEMENT. With Notes of Lessons on Objects, and on the Phenomena of Nature and Common Life. By Sarah J. Hale, late Teacher of Method, St. Katherine's Training College, Tottenham. With an Illustration. Crown 8vo, cloth, 4s. 6d.

NEEDLEWORK and CUTTING-OUT: Being Hints, Suggestions, and Notes, for the Use of Teachers in dealing with the difficulties in the Needlework Schedule. By Kate Stanley, F.R.B.S., Head-Governess and Teacher of Needlework at Whitelands College, Chelsea. With numerous Illustrations. Second Edition, Revised. Crown 8vo, cloth, 3s. 6d.

London: EDWARD STANFORD, 55 Charing Cross, S.W.

Printed by Richard Clay and Sons, at 7 and 8 Bread Street Hill, Queen Victoria Street, in the City of London, and Published by Macmillan and Co., at the Office, 29 and 30 Bedford Street Covent Garden.—Thursday, January 20, 1887.

THE JOURNAL OF PHYSIOLOGY.

Edited, with the Co-operation in England of
Prof. W. RUTHERFORD, F.R.S., of Edinburgh, Prof. J. BURDON-SANDERSON, F.R.S., of Oxford; and in America of
Prof. H. P. BOWDITCH, of Boston, Prof. H. NEWELL MARTIN, F.R.S., of Baltimore; Prof. H. C. WOOD, of Philadelphia,

BY

MICHAEL FOSTER, M.D., F.R.S.

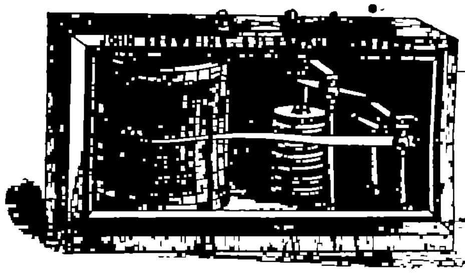
THE CAMBRIDGE SCIENTIFIC INSTRUMENT COMPANY,
CAMBRIDGE.

BRITISH MUSEUM (NATURAL HISTORY).

An ASSISTANTSHIP of the Second Class in the Department of Geology is now Vacant. Limits of age, 18 to 30 years. Salary commences at 120*l.* per annum. Candidates will be required to undergo a competitive examination by the Civil Service Commissioners in general subjects as well as Geology and Palæontology.—Applications, accompanied by two or three Testimonials, to be sent to Prof. Flower, Director, Natural History Museum, Cromwell Road, London, S.W., from whom further information can be obtained.

January 25, 1887.

THE NEW
SELF-REGISTERING ANEROID BAROMETER.



This instrument has neither a spring nor chain. The motive power of the Barometer is obtained from seven vacuum-chambers.

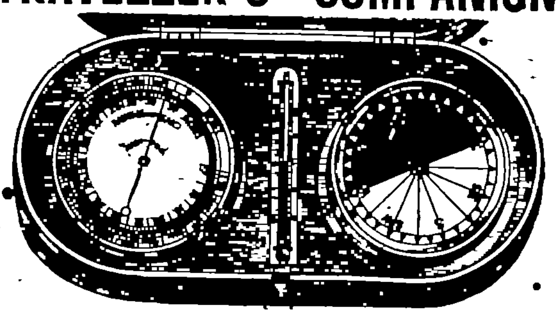
It will register automatically with ink on a diagram, by means of an eight-day clock motion contained in the drum, the fluctuations of the Barometer *for a week.* An illustrated description sent post free.

A new and greatly improved diagram has just been prepared at the suggestion of Mr. Latimer Clark, C.E. A supply of these diagrams for a year will be sent with each instrument.

PRICE £6 0s. 0d.

JOHN BROWNING,
68 STRAND, LONDON, W.C.

TRAVELLER'S COMPANION,



ANEROID BAROMETER with Altitude Scale, COMPASS with Patent Dial, and THERMOMETER having Fahrenheit and Centigrade Scale.
Price 5 to 8 Guineas.

Illustrated Price Lists Posted Free to all Parts of the World.

NEGRETTI & ZAMBRA,
Scientific Instrument Makers to the Queen,
HOLBORN VIADUCT.
Branches:—45 CORNHILL; 122 REGENT STREET.
Photographers at the CRYSTAL PALACE.
N. and Z.'s Large Illustrated Catalogue, 1200 Engravings. Price 5s. 6d.
Telephone No. 6983. Telegraphic Address: Negretti, London.

GUY'S HOSPITAL MEDICAL SCHOOL.

UNIVERSITY OF LONDON, PRELIMINARY SCIENTIFIC (M.B.) EXAMINATION.

Instruction is given in all the subjects of the above Examination at GUY'S HOSPITAL during the Winter and Summer Sessions. The Fee for the whole Course is 10 Guineas. The Class is not confined to Students of the Hospital.

For further particulars, apply to the DEAN, Guy's Hospital, Southwark S.E.

ELECTRICAL ENGINEERING.

CITY AND GUILDS OF LONDON INSTITUTE.

The Courses of Technical Instruction at the Central Institution, Exhibition Road, S.W., are open to persons desirous of studying any branch of ELECTRICAL ENGINEERING. The Instruction, under the general direction of Prof. AYRTON, F.R.S., comprises Lectures and Practice in the Laboratories and Dynamo-Room. For particulars apply at Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

DYNAMO-ELECTRIC MACHINERY.

A Special Course of PRACTICAL DEMONSTRATIONS in the TESTING of the POWER and EFFICIENCY of DYNAMOS and MOTORS will be given by Prof. AYRTON, F.R.S., at the CENTRAL INSTITUTION of the CITY and GUILDS of LONDON INSTITUTE, commencing on FRIDAY, February 4, at 5 p.m. Fee for the Course £1 11*s.* 6*d.*, or to Registered Teachers of the Institute 15*s.* For particulars apply at Exhibition Road, S.W., or at Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

A FRENCH GENTLEMAN, with First-rate Scholastic Recommendations, has a French Class for Army Pupils at 2 Colville Gardens, Bayswater. He and his wife also receive as Boarders two or three Young Men who wish to study the language for business or conversational purposes.—Address M. ALFRED VIGIER, Swanley, Kent.

FOR SALE.—About 728 Numbers, loose, of NATURE, including Indexes from 1873 to 1886. What offers?—Address J. S. DISMORE, Stewart House, Gravesend.

VOLS. XXVIII. to XXXIV. of NATURE for Sale; in good condition; half price.—H. D. BERRIDGE, 203 Belle Vue Road, Leeds.

SIX PRIZE MEDALS

AWARDED FOR GEOLOGICAL COLLECTIONS.

Geological Collections especially adapted for Teaching as supplied to Science and Art Department, and used by all Lecturers and Teachers in Great Britain, &c.

New and Rare Minerals constantly arriving from all parts for selection of Single Specimens.

ROCK SECTIONS AND ROCK SPECIMENS:

The Largest Variety in England.

New Catalogues and Lists on application to—

JAMES R. GREGORY,

88 CHARLOTTE STREET, FITZROY SQUARE, LONDON.

Established 27 Years in London.

YORK'S

OPTICAL LANTERN SLIDES.

Seven Medals have been awarded.

In addition to the thousands of subjects, embracing Travel, every branch of Science, &c., &c., and the much appreciated Popular Recitations, Moral, Comic, and Temperance Tales illustrated by Life Models, the following are added to their seventeenth Annual Catalogue:—

Washington to the Yellowstone Park; Washington City: English and Italian Lakes; Venice; Algiers; Holland; Burmah; Channel Islands; Norway; the Improved Comic Slips; and the following from Life Models—"Curfew must not Ring To-night," and the popular Temperance Tale, "Little Tiz."

Sold by all the Leading Opticians in the United Kingdom, through whom please order.

YORK & SON,

87 Lancaster Road, Notting Hill, London, W.

BOOKS (Secondhand), Miscellaneous, Remainders, &c.—C. HERBERT, English and Foreign Bookseller, 319 Goswell Road, London, E.C. Catalogue free on receipt of two stamps. Libraries, Old Books, and Parchments purchased.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to

THOMAS BOLTON, 57 NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers Trachelius ovum, with drawing and description. He also sent out Trout Ova and Fry, Carchesium polypinum, Volvox globator, Glass Larva, Entomostraca, Spongilla fluviatilis, Desmids, Difflugia, also Hydra, Amoeba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1*s.*, *or Twelve Tubes for* 10*s.* 6*d.*

Portfolio of Drawings, Eleven Parts, 1*s.* each.

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1*s.* per bottle, with full instructions for use, from most Opticians. Post free for 1*s.* 3*d.* from

EDWARD WARD, 249 Oxford Street, Manchester. [503

ROCKS, MINERALS, FOSSILS.

F. H. BUTLER,

Assoc. R. S. Mines Lond., M.A. Oxon., L.S.A. Lond., &c.,

Successor to the late R. TALLING,

180 BROMPTON ROAD, LONDON, S.W.

RECENTLY RECEIVED:—Fine Quartz Catseyes, Rubies, pink and other Sapphires, Wheal Alfred Pyromorphite, groups of exceptionally large Crystals of Barytes, well-crystallised Anorthite, Meionite, and other Vesuvian Minerals, Eskdale Crustacea, and rare American Crinoids and Trilobites.

MINERALS, FOSSILS, ROCKS, MICROSCOPIC OBJECTS.

RECENT SHELLS, CRUSTACEA, ECHINODERMS, CABINETS, GLASS-CAPPED BOXES, GEOLOGISTS' HAMMERS, NATURALISTS' DREDGES, &c.

THOMAS D. RUSSELL,

PRIZE MEDALLIST, HEALTH EXHIBITION,

78 NEWGATE STREET, LONDON, E.C.

MINERALOGY AND GEOLOGY.

CHOICE SPECIMENS FOR MUSEUMS AND PRIVATE COLLECTORS: BERYLS, TOPAZES, RUTILES ON MATRIX, CELESTINE, OPALS, &c., &c.

RARE MINERALS FOR SCIENTIFIC RESEARCH; COLLECTIONS FOR STUDENTS AND PROSPECTORS.

VERY FINE POLISHED SECTIONS OF AMMONITES AND NAUTILI.

NEW SERIES OF ROCKS. MICROSCOPIC SLIDES.

Hammers, Chisels, and Blow-pipe Apparatus.

PRIVATE LESSONS AND EVENING CLASSES.

CATALOGUES ON APPLICATION.

A NEW BOOK BY MR. J. NORMAN LOCKYER.

THE CHEMISTRY OF THE SUN.

By J. NORMAN LOCKYER, F.R.S.,

Correspondant of the Institute of France, Foreign Member of the Academy of the Lyncei of Rome, &c., &c., &c.

With Illustrations, Demy 8vo, 14*s*.

The *Times* says:—

"The phrase (the chemistry of the sun) would have had no meaning half a century ago, and the results achieved, as described in Mr. Lockyer's clear, emphatic, and unconventional style, must far exceed the most sanguine dreams of early spectroscopists. They certainly scatter many of the fine fancies which the poets have woven round the face of our 'spotless' luminary; but have given us in their place facts which no poet could ever have approached in his wildest imaginings. . . . . Mr. Lockyer begins at the beginning, and traces carefully and with clear deliberation the progress of solar spectroscopy from the time of Kepler to the present day. . . . . We have only been able in the most summary manner to refer to some of the points of interest in this new volume, the numerous illustrations in which deserve a word of praise."

The *Scotsman* says:—

"No man in this country can surpass Mr. Lockyer in the rare combination of painstaking accuracy in experimental work, sterling impartiality of judgment, and brilliant clearness in the expression of his opinions. His numerous published works have assigned him the highest place as an authority on solar physics. . . . . The author's work is to be highly commended; whatever conclusions scientific critics may arrive at as to the value of the hypothesis so ably advocated, there can be no two opinions about the uniform modesty and courteous respect for others which breathe through every page of the volume; the brilliant but clear style of the language in which his thoughts are clothed; the exemplary enthusiasm by which he carries his readers on over much which otherwise would be hard and dry; and the genuine scientific scholarship which never courts the tactics of the mountebank."

MACMILLAN & CO., LONDON.

FOURTH EDITION, Revised and Considerably Enlarged.

SPECTRUM ANALYSIS.

SIX LECTURES DELIVERED IN 1868 BEFORE THE SOCIETY OF APOTHECARIES OF LONDON.

BY

SIR HENRY E. ROSCOE, LL.D. F.R.S.,

FOURTH EDITION, REVISED AND CONSIDERABLY ENLARGED BY THE AUTHOR AND

ARTHUR SCHUSTER, Ph.D., F.R.S.,

Professor of Applied Mathematics in Owens College, Victoria University.

With Appendices and numerous Illustrations and Plates. Medium 8vo, 21*s*.

MACMILLAN & CO., LONDON.

ADAPTED TO THE NEW BRITISH PHARMACOPŒIA, 1885.

Medium 8vo, price 21*s*.

A TEXT-BOOK OF PHARMACOLOGY, THERAPEUTICS, and MATERIA MEDICA.

By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S., Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; Late Examiner in the University of Edinburgh.

ADAPTED TO THE UNITED STATES PHARMACOPŒIA BY F. H. WILLIAMS, M.D., BOSTON, MASS.

"It is simply a mine of wealth both for students and practitioners. It is thoroughly practical and thoroughly reliable. . . . It is undoubtedly the best treatise on the subject in the English language."—*British Medical Journal.*

"A work which marks a distinct epoch, a turning-point in the history of medicine. It is not a mere compilation, . . . but it is essentially a new departure breaking away from well-worn tracks into a new and almost unknown region."—*Medical Times and Gazette.*

BY THE SAME AUTHOR.

DISORDERS OF DIGESTION: THEIR CONSEQUENCES AND TREATMENT

This Work contains, in addition to the Lettsomian Lectures, a number of other Papers by the Author on similar subjects.

8vo, 10*s*. 6*d*.

"Distinguished by accurate observation and original thinking, these papers have been largely instrumental in moulding current medical opinion in regard to many of the subjects with which they are concerned."—*Edinburgh Medical Journal.*

"We can cordially recommend the volume, as one which combines much practical and technical information and sound common-sense."—*London Medical Record.*

ALUMINIUM:

ITS HISTORY, OCCURRENCE, PROPERTIES, METALLURGY, AND APPLICATIONS, INCLUDING ITS ALLOYS.

By JOSEPH W. RICHARDS, A.C., Chemist and Practical Metallurgist.

CONTENTS.—PART I.—History of Aluminium.

PART II.—Occurrence in Nature: Beauxite, Cryolite, Corundum

PART III.—Properties. Physical Properties. Commercial Aluminium, Colour, Mat; Lustre, Odour; Taste, Malleability, Ductility, Tenacity; Elasticity, Hardness, Sonorousness, Density; Fusibility, Non-Volatility; Electric Conductivity; Thermal Conductivity; Specific Heat, Magnetism, Crystalline Form. Chemical Properties: Action of Air, Water, Sulphuretted Hydrogen and Sulphur, Sulphuric Acid, Nitric Acid, Hydrochloric Acid, Caustic Alkalies, Organic Acids, Vinegar, &c., Solutions of Metallic Salts, Nitre, Silicates and Borates, Fluorspar, Calcium Phosphate, Sodium Chloride, Metallic Oxides, Animal Matters, Sulphate of Potash, Sulphate of Soda, Hydrogen, Nitrogen, Sulphur, Chlorine, Carbon, Bromine, Fluorine, Carbonates of Potash and Soda, General Observations.

PART IV.—Metallurgy (Experimental Stage): Oerstedt, Wohler, Deville, H. Rose, Dr. Percy, Gerhard; (Practical Stage): General Remarks, Metallurgy of Sodium, Davy, Gay-Lussac and Thenard, Curandan, Brünner, Donny and Mareska, Thwig, R. Wagner, Dumas, Castner, Jablochkoff; Manufacture of Alumina. Tilghmann's Process, From Cryolite, Dry Way, Wet Way, Manufacture of Double Chloride of Aluminium and Sodium, Process in use at Salindres, Cost of Same, Webster's Process, Grobsilher's Frishmuth's, Niewerth's; Reduction by other Agents than Sodium, Cyanogen (Corbelli), Hydrogen (Gerhard), Carburetted Hydrogen (Fleury, Petitjean), Double Reactions (Comenge, Johnson, Niewerth), Carbon and Carbonic Acid (Morris), Carbon (Chapelle, Reinar, Cowles), Iron (Lauterborn, Niewerth, Thompson, Calvert, Johnson, Benson, Evrard, Ostberg), Copper (Calvert and Johnson, Benson), Zinc (Bassett, Wedding, Seymour), Lead (Wilde, Kagensbusch), Manganese (Weldon), Electricity (Deville, Bunsen, Grätzel, &c.), Working in Aluminium; Melting, Casting, Freeing from Slag, Purification, Uses of Aluminium, Soldering, Veneering with Aluminium, Gilding and Silvering Aluminium.

PART V.—Alloys of Aluminium. General Remarks: Silicon, Mercury, Copper, Iron, Zinc, Tin, Lead, Antimony, Bismuth, Nickel, Silver, Gold, Platinum, Cadmium, Boron, Carbon, Gallium, Titanium, Wolfram, Molybdenum, Manganese, Sodium, Nitrogen. Appendix.

(UNLIKE MNEMONICS),
And Cure of Mind Wandering.

Any Book Learned in One Reading Great inducements to Correspondence Classes.

New Prospectus from Prof LOISETTE, 37 New Oxford Street, London.

NORTH BRITISH AGRICULTURIST,

the chief Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 14s.

Offices—377 High Street, Edinburgh; and 145 Queen Victoria Street, London, E.C. Money Orders payable to C. and R. ANDERSON

THE ENTOMOLOGIST'S MONTHLY MAGAZINE.

Price Sixpence, Monthly, 24 pages 8vo, with occasional Illustrations.

Conducted by C. G. BARRETT, J W. DOUGLAS, W. W. FOWLER, M.A., F.L.S., R. MCLACHLAN, F.R.S, E. SAUNDERS, F.L.S., and H. T. STAINTON, F.R.S.

This Magazine, commenced in 1864, contains standard articles and notes on all subjects connected with Entomology, and especially on the Insects of the British Isles.

Subscription—Six Shillings per Volume, post free. The volumes commence with the June number in each year.

Vols. I. to VI. (strongly bound in cloth) may be obtained by purchasers of the entire set to date, at the increased price of 10s. each; the succeeding vols. may be had separately or together, at 7s. each.

London: GURNEY & JACKSON (Mr. Van Voorst's successors),
1, Paternoster Row.

N.B.—Communications, &c., should be sent to the Editors at the above address.

On the 1st of every Month, price Sixpence.

THE ENTOMOLOGIST:

AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOGY.

Edited by JOHN T. CARRINGTON,
With the Assistance of
FREDERICK BOND, F.Z.S. | RICHARD SOUTH.
EDWARD A. FITCH, F.L.S. | J. JENNER WEIR, F.L.S.
F. BUCHANAN WHITE, M.D.

Contains Articles by well-known Entomologists on all Branches of the Science; on Insects injurious or beneficial to Farm or Garden; Notes on Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthly Lists of Duplicates and Desiderata.

WOODCUT ILLUSTRATIONS and occasional LITHOGRAPHED and CHROMO-LITHOGRAPHED PLATES.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

J. C. BUCKNILL, M.D., F R.S, THOMAS BUZZARD, M.D., F.R.C P, SIR J. CRICHTON-BROWNE, M D., F.R S., DAVID FERRIER, M.D., F.R S, J HUGHLINGS-JACKSON, M D., F.R.S, and JAMES ROSS, M.D., F.R.C.P.

ACTING EDITOR:
A. DE WATTEVILLE, M A, M.D, B.Sc

Contents

ORIGINAL ARTICLES—
Rotation of the Great Brain By Alex Hill, M A., M D
Some of the Relationships between Epilepsy and Insanity By C. H. Savage, M D, F R.C.P.
On Pseudo-Tabes from Arsenical Poisoning, with a Consideration of the Pathology of Arsenical Paralysis. By Charles L. Dana, A.M., M.D, New York.
Coma. By Charles Mercier, M.B.
A Contribution to the Pathology of Dreams and of Hysterical Paralysis. By Ch. Féré, M.D.
On Changes in Nervous System after Amputation of Limbs, with Bibliography and Recent Case. By Ernest S. Reynolds, M.D. (London)
Cases of Injury to the Cervical Region of the Spinal Cord. By William Thorburn, M.D., B.S. (Lond.), F R.C.S
Sequel to a "Case of Ophthalmoplegia, complicated with various other Affections of the Nervous System." By J. S. Bristowe, M.D, F.R S

CLINICAL CASES—
A Case of Hystero-Epileptoid Attacks, with Convulsions produced by Local Irritation of the Skin. By G. Parker, M.D
A Case illustrating the Differential Diagnosis of Tumour of the Cord and Tumour of the Cauda Equina. By James Oliver, M.B., F.R.S. (Edin.).

ABSTRACTS OF BRITISH AND FOREIGN JOURNALS—
Wundt's Philosophische Studien. By J. McCattell, Ph.D.
Abstracts of Papers on Nervous Diseases published in St. Thomas's Hospital Reports from 1865 to 1884 (Vols. VI. to XIV. inclusive). By W. B. Hadden, M.D. (Lond.).
Westphal on a Peculiar Group of Symptoms—Rumpf on Syphilis, Infantile Paralysis, and Cerebellar Atrophy—Schulz on Aphasia, Hemianopsia, Spinal Sarcoma, and Tetanus. By W. J. Dodds, M.D., D Sc.
Frew: a Report of a slight Outbreak of Epidemic Cerebrospinal Meningitis, with Notes of Six Cases—Middleton on the Pathology of Pseudo-hypertrophic Muscular Paralysis, with Remarks on a so-called Degeneration of the Nervous System—Beevor on Three Cases illustrating the Localisation of Motor Centres in the Brachial Enlargement of the Spinal Cord—Voss on a Case of Tubercular Tumour of the Cerebellum By J. A. Ormerod, M D.
Remak on a Case of Bilateral Paralysis of the Spinal Accessory Nerve—Hughes Bennett on Locomotor Ataxy, without Disease of the Posterior Columns of the Spinal Cord; and on a Case of Cerebral Tumour, the Surgical Treatment by Rickman J. Godlee. By J. F. Pringle, M.D.

MACMILLAN & CO., LONDON.

THE ZOOLOGIST:

A MONTHLY MAGAZINE OF NATURAL HISTORY.

Third Series. Edited by J. E. HARTING, F.L.S., F.Z.S., Member of the British Ornithologists' Union; contains—

Original Articles by well-known naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds; occurrence of rare birds; distribution and migration of British fresh-water fish, new or rare marine fish; local aquaria; British reptiles; British land and fresh-water mollusca, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts

Diary of Societies.

LONDON

THURSDAY, FEBRUARY 3.

ROYAL SOCIETY, at 4.30.—(1) On the Waves produced by a Single Impulse in Water of any Depth, or in a Dispersive Medium. (2) On the Formation of a Vortex or Vortices by the Motion of a Solid through an Inviscid Incompressible Fluid : Sir William Thomson, F.R.S.—On Proterosaurus speneri (von Meyer) : Prof. H. G. Seeley, F.R.S.

CHEMICAL SOCIETY, at 8.—Ballot for the Election of Fellows.—An Explanation of the Laws which govern Substitution in the Case of Benzenoid Compounds : Dr. Armstrong.—The Decomposition of Potassium Chlorate and Perchlorate by Heat : Dr. Percy Frankland and J. Dingwall.—The Synthetical Formation of Closed Carbon Chains—Part I. Some Derivatives of Tetramethylene : Dr. W. H. Perkin, Jun., and H. Coleman ; Part II. Some Derivatives of Pentamethylene : Dr. W. H. Perkin, Jun.

LINNEAN SOCIETY, at 8.—Fauna and Flora of the Afghan Boundary : Dr. Aitchison.

ROYAL INSTITUTION, at 3.—Molecular Forces : Prof. A. W. Rücker, M.A., F.R.S.

FRIDAY, FEBRUARY 4.

GEOLOGISTS' ASSOCIATION, at 7.30.—Annual General Meeting.—On the Recent Volcanic Outburst in New Zealand : Wm. Lant Carpenter.—On Agates and their Formation : W. J. Abbott.

INSTITUTION OF CIVIL ENGINEERS, at 7.30.—Recent Researches in Friction (part 2) : John Goodman.

ROYAL INSTITUTION, at 9.—Some Unpublished Records of the City of London : Edwin Freshfield, LL.D.

SATURDAY, FEBRUARY 5.

ROYAL INSTITUTION, at 3.—Modern Composers of Classical Song—Johannes Brahms (with Vocal Illustrations) : Carl Armbruster.

MONDAY, FEBRUARY 7.

VICTORIA INSTITUTE, at 8.—The Pedigree of Coral Reefs : S. R. Pattison.

ODONTOLOGICAL SOCIETY, at 8.—President's Inaugural Address.

ROYAL INSTITUTION, at 5.—General Monthly Meeting.

LONDON INSTITUTION, at 5.—Art in the Past : W. B. Richmond.

TUESDAY, FEBRUARY 8.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—Notes on the Tribes of the Nile Valley North of Khartum : Lieutenant-Colonel Sir Charles Wilson, R.E., K.C.B.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Fermentation in its Relation to Bread-making : W. Jago.

PHOTOGRAPHIC SOCIETY, at 8.—Anniversary.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Adjourned Discussion upon the Papers by Mr. Dibdin and Mr. Santo Crimp, on "Sewage-Sludge."

ROYAL INSTITUTION, at 3.—The Function of Respiration : Prof. Arthur Gamgee, F.R.S.

WEDNESDAY, FEBRUARY 9.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Recent Optical Improvements in the Microscope ; and the Operation of the Darwinian Law amongst the Minutest Organisms : Rev. Dr. Dallinger, F.R.S.

GEOLOGICAL SOCIETY, at 8.—Evidence of Glacial Action in the Carboniferous and Hawkesbury Series, New South Wales : T. W. Edgeworth David.—The Eruption of Mount Tarawera : Capt. F. W. Hutton.—The Terraces of Rotomahana, New Zealand : Josiah Martin.

THURSDAY, FEBRUARY 10.

ROYAL SOCIETY, at 4.30.

MATHEMATICAL SOCIETY, at 8.—On the Equation of Riccati : The President.—The Ortho-centroidal Circle : R. Tucker.—On Polygons inscribed in a Quadric and circumscribed about two Confocal Quadrics : R. A. Roberts.—On the Binomial Equation $x^p - 1 = 0$; Quinquisection : Prof. Tanner.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS, at 8.—Telephonic Investigations : Prof. Silvanus P. Thompson.

ATHENÆUM SOCIETY, at 8.

ROYAL INSTITUTION, at 3.—Molecular Forces : Prof. A. W. Rucker, F.R.S.

LONDON INSTITUTION, at 6.—Electric Bells, I. : Prof. Silvanus Thompson, Ph.D.

FRIDAY, FEBRUARY 11.

ROYAL ASTRONOMICAL SOCIETY, at 3.—Anniversary.

ROYAL INSTITUTION, at 9.—Gilded Chrysallides : Edward B. Poulton.

SATURDAY, FEBRUARY 12.

PHYSICAL SOCIETY, at 3.—Annual General Meeting.—Note on the Tenacity of Spun Glass : E. Gibson and R. A. Gregory.

ROYAL INSTITUTION, at 3.—Modern Composers of Classical Song—Rubinstein, Raff, and Grieg (with Vocal Illustrations) : Carl Armbruster.

JAMES HOW & CO., 73 FARRINGDON STREET, LONDON.

VAN HOUTEN'S
pure soluble COCOA
is the best and, although a little dearer, really the cheapest in the end.

The *British Medical Journal* says:—"'VAN HOUTEN'S COCOA' is admirable. In flavour it is perfect, and it is so pure, well prepared, and rich," &c., &c.

A NEW BOOK BY MR. J. NORMAN LOCKYER.

THE CHEMISTRY OF THE SUN.

BY J. NORMAN LOCKYER, F.R.S.,

Correspondant of the Institute of France, Foreign Member of the Academy of the Lyncei of Rome, &c., &c., &c.

With Illustrations, Demy 8vo, 14*s.*

The *Times* says:—

"The phrase (the chemistry of the sun) would have had no meaning half a century ago, and the results achieved, as described in Mr. Lockyer's clear, emphatic, and unconventional style, must far exceed the most sanguine dreams of early spectroscopists. They certainly scatter many of the fine fancies which the poets have woven round the face of our 'spotless' luminary; but have given us in their place facts which no poet could ever have approached in his wildest imaginings. . . . . Mr. Lockyer begins at the beginning, and traces carefully and with clear deliberation the progress of solar spectroscopy from the time of Kepler to the present day. . . . . We have only been able in the most summary manner to refer to some of the points of interest in this new volume, the numerous illustrations in which deserve a word of praise."

The *Scotsman* says:—

"No man in this country can surpass Mr. Lockyer in the rare combination of painstaking accuracy in experimental work, sterling impartiality of judgment, and brilliant clearness in the expression of his opinions. His numerous published works have assigned him the highest place as an authority on solar physics. . . . . The author's work is to be highly commended; whatever conclusions scientific critics may arrive at as to the value of the hypothesis so ably advocated, there can be no two opinions about the uniform modesty and courteous respect for others which breathe through every page of the volume; the brilliant but clear style of the language in which his thoughts are clothed; the exemplary enthusiasm by which he carries his readers on over much which otherwise would be hard and dry; and the genuine scientific scholarship which never courts the tactics of the mountebank."

the Quantitative Estimation of Chemical Substances by Measure, applied to Liquids, Solids, and Gases. Adapted to the Requirements of Pure Chemical Research, Pathological Chemistry, Pharmacy, Metallurgy, Manufacturing Chemistry, Photography, &c., and for the Valuation of Substances used in Commerce, Agriculture, and the Arts.

Vol. II., Second Edition, Revised and Enlarged, 8vo, 17*s*. 6*d*., now ready.

COMMERCIAL ORGANIC ANALYSIS. By ALFRED H. ALLEN,

F.I.C., F.C.S.

CONTENTS:—Fixed Oils, Lard, Tallow, Butter, Waxes, Lubricating Oils, Fatty Acids, Soaps, Glycerin, Hydrocarbons, Shale Oil, Coal Tar, Asphalt, Petroleum, Kerosene, Paraffin, Essential Oils, Turpentine, Resins, Rosin Oil, Benzols and Naphthas, Naphthalene, Anthracene, Carbolic Acid, Carbolic Powders, Creosote Oils, Creosote, &c., &c.

Vol. I. (price 14*s*.) contains Alcohols, Ethers, and other Neutral Alcoholic Derivatives, Sugars, Starch and its Isomers, Vegetable Acids, &c., &c.

Vol. III., completing the work, is in preparation.

Sixth Edition, with Engravings, 8vo, 8*s*. 6*d*.

VALENTIN'S QUALITATIVE ANALYSIS. Revised and Corrected

by Dr. W. R. HODGKINSON, Senior Demonstrator and Lecturer on Chemistry in the Science Schools, South Kensington, and H. M. CHAPMAN, Assistant-Demonstrator of Chemistry in the Royal School of Mines, South Kensington.

Fourth Edition, with 55 Engravings, post 8vo, 7*s*. 6*d*.

PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC

ANALYSIS, specially adapted for Colleges and Schools. By FRANK CLOWES, D.Sc., Professor of Chemistry in University College, Nottingham.

A MANUAL OF CHEMISTRY. By HENRY WATTS, B.A., F.R.S.

Vol. I. PHYSICAL AND INORGANIC CHEMISTRY. With numerous Illustrations. Crown 8vo, 9*s*.
Vol. II. ORGANIC CHEMISTRY. Edited by WILLIAM A. TILDEN, D.Sc., F.R.S. Crown 8vo, 10*s*.

*** These two volumes are based on the well-known Manual of Fownes, and form the Thirteenth Edition of that work.

Nearly 1700 pages, 8vo, 14*s*.

THE MEDICAL DIRECTORY FOR 1887; giving the Names,

Addresses, Qualifications, Appointments, Scientific Distinctions, Published Works, &c., of Medical Practitioners and Dental Licentiates in Great Britain and Ireland; also a List of Registered Practitioners Resident Abroad, with much General and Statistical Information relating to Medical Education and Medical Practice.

WOODCUT ILLUSTRATIONS and occasional LITHOGRAPHED and CHROMO-LITHOGRAPHED PLATES.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

THE CROONIAN LECTURES FOR 1886.

Price 3s. 6d.

On SOME POINTS in the PATHOLOGY

of RHEUMATISM, GOUT, and DIABETES; the Croonian Lectures for 1886, delivered at the Royal College of Physicians, London, by P. W. LATHAM, M.A., M.D., Fellow of the College, Downing Professor of Medicine in the University of Cambridge, Senior Physician to Addenbrooke's Hospital, and formerly Assistant Physician to the Westminster Hospital.

"We believe their perusal will repay every thoughtful practitioner of medicine, for Dr Latham has, we think, succeeded in the endeavour to indicate some of the changes in the nervous system, the blood, and the tissues, which may take place in diabetes, rheumatism, and gout. He has, further, drawn together a number of facts, as he says himself, and drawn certain inferences from them which, whether right or wrong, will certainly tend to a better understanding of the diseases in question."—*British Medical Journal.*

"The arguments in support of Dr. Latham's views afforded by appropriate treatment of rheumatism, gout, and diabetes by salicylic and benzoic acids and colchicum are not the least interesting part of the Croonian Lectures."—*Lancet.*

Cambridge: DEIGHTON, BELL, & CO.
London: GEORGE BELL & SONS.

Now Ready, Part XXXVI., Demy 8vo, Price 3s. 6d.

BRAIN:

A JOURNAL OF NEUROLOGY.

EDITORIAL COMMITTEE:

J. C. BUCKNILL, M.D., F.R.S., THOMAS BUZZARD, M.D., F.R.C.P., SIR J. CRICHTON-BROWNE, M.D., F.R.S., DAVID FERRIER, M.D., F.R.S., J. HUGHLINGS-JACKSON, M.D., F.R.S., and JAMES ROSS, M.D., F.R.C.P.

ACTING EDITOR:

A. DE WATTEVILLE, M.A., M.D., B.Sc.

Contents.

ORIGINAL ARTICLES—
- Rotation of the Great Brain. By Alex. Hill, M.A., M.D.
- Some of the Relationships between Epilepsy and Insanity. By C. H. Savage, M.D., F.R.C.P.
- On Pseudo-Tabes from Arsenical Poisoning, with a Consideration of the Pathology of Arsenical Paralysis. By Charles L. Dana, A.M., M.D., New York.
- Coma. By Charles Mercier, M.B.
- A Contribution to the Pathology of Dreams and of Hysterical Paralysis. By Ch. Féré, M.D.
- On Changes in Nervous System after Amputation of Limbs, with Bibliography and Recent Case. By Ernest S. Reynolds, M.D. (London).
- Cases of Injury to the Cervical Region of the Spinal Cord. By William Thorburn, M.D., B.S. (Lond.), F.R.C.S.
- Sequel to a "Case of Ophthalmoplegia, complicated with various other Affections of the Nervous System." By J. S. Bristowe, M.D., F.R.S.

CLINICAL CASES—
- A Case of Hystero-Epileptoid Attacks, with Convulsions produced by Local Irritation of the Skin. By G. Parker, M.D.
- A Case illustrating the Differential Diagnosis of Tumour of the Cord and Tumour of the Cauda Equina. By James Oliver, M.B., F.R.S. (Edin.).

ABSTRACTS OF BRITISH AND FOREIGN JOURNALS—
- Wundt's Philosophische Studien. By J. McCattell, Ph.D.
- Abstracts of Papers on Nervous Diseases published in St. Thomas's Hospital Reports from 1865 to 1884 (Vols. VI. to XIV. inclusive). By W. B. Hadden, M.D. (Lond.).
- Westphal on a Peculiar Group of Symptoms—Rumpf on Syphilis, Infantile Paralysis, and Cerebellar Atrophy—Schulz on Aphasia, Hemianopsia, Spinal Sarcoma, and Tetanus. By W. J. Dodds, M.D., D.Sc.
- Frew: a Report of a slight Outbreak of Epidemic Cerebrospinal Meningitis, with Notes of Six Cases—Middleton on the Pathology of Pseudo-hypertrophic Muscular Paralysis, with Remarks on a so-called Degeneration of the Nervous System—Beevor on Three Cases illustrating the Localisation of Motor Centres in the Brachial Enlargement of the Spinal Cord—Voss on a Case of Tubercular Tumour of the Cerebellum. By J. A. Ormerod, M.D.
- Remak on a Case of Bilateral Paralysis of the Spinal Accessory Nerve—Hughes Bennett on Locomotor Ataxy, without Disease of the Posterior Columns of the Spinal Cord; and on a Case of Cerebral Tumour the Surgical Treatment by Rickman J. Godlee. By J. F. Pringle, M.D.

MACMILLAN & CO., LONDON.

THE ZOOLOGIST:

A MONTHLY MAGAZINE OF NATURAL HISTORY.

Third Series. Edited by J. E. HARTING, F.L.S., F.Z.S., Member of the British Ornithologists' Union; contains—

Original Articles by well-known naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds; occurrence of rare birds; distribution and migration of British fresh-water fish; new or rare marine fish; local aquaria; British reptiles; British land and fresh-water mollusca, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts.

JOHN VAN VOORST, 1 Paternoster Row.

THE NEW HOME AND COLONIAL PERIODICAL.

The JANUARY and FEBRUARY NUMBERS of

MURRAY'S MAGAZINE

are now PUBLISHED, and contain the following interesting and ORIGINAL PAPERS.

LORD BYRON'S LAST VERSES, written at MISSOLONGHI a few days before his death.
LORD BYRON'S Recollections of MADAME DE STAEL.
LORD BYRON'S Poetical Introduction to LARA.
LORD BYRON'S LAST WORDS ON GREECE.
SIR WALTER SCOTT'S Letter to Lord Byron on his Poem of the "CORSAIR."
WILLIAM GIFFORD'S Letter to Lord Byron on "CHILDE HAROLD."
NEW NOVEL, "MAJOR LAWRENCE," by the Hon. EMILY LAWLESS, Author of "HURRISH."
MR. MATTHEW ARNOLD on GENERAL GRANT.
THE BISHOP OF CARLISLE on the "CHURCH HOUSE."
LADY MACDONALD'S TRIP by CAR and by COW-CATCHER at the opening of the CANADIAN PACIFIC RAILWAY.
A DAY'S COVERT SHOOTING IN JANUARY, by E. S. H.
A SKETCH FROM LIFE of AN IRISH PARISH PRIEST.

MURRAY'S MAGAZINE is published MONTHLY at ONE SHILLING, and can be had at all BOOKSELLERS and RAILWAY STALLS.

A TEXT-BOOK OF
PATHOLOGICAL ANATOMY AND PATHOGENESIS.
By ERNST ZIEGLER, Professor of Pathological Anatomy in the University of Tubingen.
Translated and Edited for English Students by DONALD MACALISTER, M.A., M.D., B.Sc., F.R.C.P., Fellow and Medical Lecturer of St. John's College, Cambridge, Physician to Addenbrooke's Hospital, and University Lecturer in Medicine. With numerous Illustrations. PART II.—SPECIAL PATHOLOGICAL ANATOMY. Sections IX.-XII. 8vo. 12s. 6d.
Part I.—General Pathological Anatomy. Second Edition. 12s. 6d. Part II.—Special Pathological Anatomy. Sections I.-VIII. Second Edition. 12s. 6d. Sections IX.-XII. 12s. 6d.

A TREATISE ON CHEMISTRY.
By Sir H. E. ROSCOE, F.R.S.; and C. SCHORLEMMER, F.R.S.,
Professor of Chemistry in the Victoria University, Owens College, Manchester. With Illustrations. VOLUME III.—ORGANIC CHEMISTRY. Part III. Demy 8vo. 18s.
Volumes I. and II.—INORGANIC CHEMISTRY. Vol. I.—The Non-Metallic Elements. With a Portrait of DALTON, Engraved by C. H. JEENS. 21s. Vol. II. Part I.—Metals. 18s. Vol. II. Part II.—Metals. 18s. Vol. III. Three Parts.—ORGANIC CHEMISTRY. Parts I. and II. 21s. each. Part III. 18s.
MACMILLAN & CO., LONDON.

A NEW BOOK BY MR. J. NORMAN LOCKYER.

THE CHEMISTRY OF THE SUN.

By J. NORMAN LOCKYER, F.R.S.,

Correspondant of the Institute of France, Foreign Member of the Academy of the Lyncei of Rome, &c., &c., &c.

With Illustrations, Demy 8vo, 14*s.*

The *Times* says:—

"The phrase (the chemistry of the sun) would have had no meaning half a century ago, and the results achieved, as described in Mr. Lockyer's clear, emphatic, and unconventional style, must far exceed the most sanguine dreams of early spectroscopists. They certainly scatter many of the fine fancies which the poets have woven round the face of our 'spotless' luminary; but have given us in their place facts which no poet could ever have approached in his wildest imaginings. . . . . Mr. Lockyer begins at the beginning, and traces carefully and with clear deliberation the progress of solar spectroscopy from the time of Kepler to the present day. . . . . We have only been able in the most summary manner to refer to some of the points of interest in this new volume, the numerous illustrations in which deserve a word of praise."

The *Scotsman* says:—

"No man in this country can surpass Mr. Lockyer in the rare combination of painstaking accuracy in experimental work, sterling impartiality of judgment, and brilliant clearness in the expression of his opinions. His numerous published works have assigned him the highest place as an authority on solar physics. . . . The author's work is to be highly commended; whatever conclusions scientific critics may arrive at as to the value of the hypothesis so ably advocated, there can be no two opinions about the uniform modesty and courteous respect for others which breathe through every page of the volume; the brilliant but clear style of the language in which his thoughts are clothed; the exemplary enthusiasm by which he carries his readers on over much which otherwise would be hard and dry; and the genuine scientific scholarship which never courts the tactics of the mountebank."

MACMILLAN & CO., LONDON.

Now ready, Second Edition. Third Edition in the Press.

ADAPTED TO THE NEW BRITISH PHARMACOPŒIA, 1885.

Medium 8vo, price 21*s.*

A TEXT-BOOK OF PHARMACOLOGY, THERAPEUTICS, and MATERIA MEDICA.

By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S., Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; Late Examiner in the University of Edinburgh.

ADAPTED TO THE UNITED STATES PHARMACOPŒIA BY F. H. WILLIAMS, M.D., BOSTON, MASS.

"It is simply a mine of wealth both for students and practitioners. It is thoroughly practical and thoroughly reliable. . . . It is undoubtedly the best treatise on the subject in the English language."—*British Medical Journal.*

"A work which marks a distinct epoch, a turning-point in the history of medicine. It is not a mere compilation, . . . but it is essentially a new departure breaking away from well-worn tracks into a new and almost unknown region."—*Medical Times and Gazette.*

BY THE SAME AUTHOR.

DISORDERS OF DIGESTION: THEIR CONSEQUENCES AND TREATMENT.

This Work contains, in addition to the Lettsomian Lectures, a number of other Papers by the Author on similar subjects.

8vo, 10*s.* 6*d.*

"Distinguished by accurate observation and original thinking, these papers have been largely instrumental in moulding current medical opinion in regard to many of the subjects with which they are concerned."—*Edinburgh Medical Journal.*

"We can cordially recommend the volume, as one which combines much practical and technical information and sound common-sense."—*London Medical Record.*

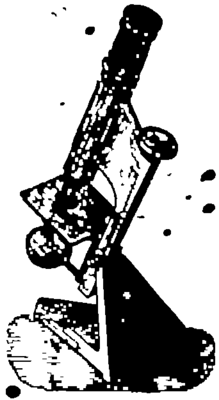
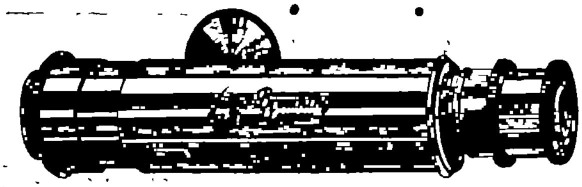
GOLD MEDAL,
International Inventions Exhibition, 1885.



GRACE'S NEW DIRECT VISION SPECTROSCOPE.

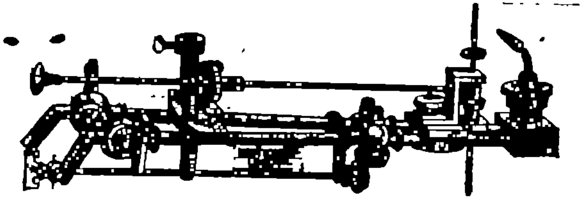


Mr. JOHN BROWNING begs to direct attention to the advantages of this very powerful, portable, and efficient Instrument, which will divide the Sodium lines or the D lines in the Solar Spectrum, and show the Rain-Band *as Separate Lines*; it is provided with a fine motion focusing arrangement, and it is applicable to every purpose for which a Direct Vision Spectroscope can be used.

Price in Morocco Leather Case, £3 8s. 6d.
Illustrated Catalogue of Spectroscopes sent post free, Sixpence.

JOHN BROWNING,
Optical and Physical Instrument Maker to H.M. Government,
63 STRAND, LONDON, W.C.

NEW PATTERN OXY-HYDROGEN JET
FOR LIME-LIGHT LANTERN.



This jet, designed by Lewis Wright, Esq., gives a *most powerful light*, with a minimum of trouble. The lime-pin, of Bessemer steel, has a deep spiral cut in it, to which Newton's new check-action is fitted. By this arrangement, the whole lime-surface is used, yet the light never impinges twice on the same spot.

A new "cut-off," devised by Andrew Pringle, Esq., is also fitted to these jets, by which the light can be turned up or down without altering the taps.

Can be seen at work at 3 Fleet Street.

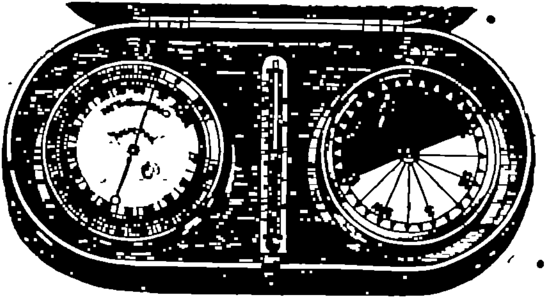
Price, best workmanship, 47s. 6d., as supplied to A. Pringle, Esq., who writes:—

"I write to let you know of the great success of the jet you made for me. It gives a grand light, and does not crack the limes as most jets do. Regarding the cut-off, every time I use it I like it better."

Price, without "cut-off" (as supplied to L. Wright, Esq.), 32s. 6d.

NEWTON & CO., 3 Fleet Street, London E.C.

TRAVELLER'S COMPANION.



ANEROID BAROMETER with Altitude Scale, COMPASS with Patent Dial, and THERMOMETER having Fahrenheit and Centigrade Scale

EXAMPLES OF EXERCISES IN NATURAL PHILOSOPHY, given in the Natural Philosophy Class of Glasgow University from 1865 to 1885, with Indications how to answer them. By MAGNUS MACLEAN, M.A., Assistant to the Professor of Natural Philosophy in the University of Glasgow.

Glasgow: JAMES MACLEHOSE & SONS, 61 St. Vincent Street.

STANDARD SCIENTIFIC WORKS.

WORKS BY JOHN TYNDALL, D.C.L., LL.D., F.R.S., &c.

FRAGMENTS of SCIENCE. 2 Vols. Crown 8vo. 16s.

HEAT a MODE of MOTION. Crown 8vo. 12s.

SOUND. With 204 Woodcuts. Crown 8vo. 10s. 6d.

ESSAYS on the FLOATING MATTER of the AIR in RELATION to PUTREFACTION and INFECTION. With 24 Woodcuts. Crown 8vo. 7s. 6d.

LECTURES on LIGHT, delivered in America in 1872 and 1873. With 57 Diagrams Crown 8vo. 5s.

LESSONS in ELECTRICITY at the ROYAL INSTITUTION, 1875-76. With 58 Woodcuts. Crown 8vo. 2s. 6d.

NOTES of a COURSE of SEVEN LECTURES on ELECTRICAL PHENOMENA and THEORIES, delivered at the Royal Institution. Crown 8vo. 1s. Sewed, 1s. 6d. Cloth

NOTES of a COURSE of NINE LECTURES on LIGHT, delivered at the Royal Institution. Crown 8vo. 1s. Sewed, 1s. 6d. Cloth.

FARADAY as a DISCOVERER. Fcap. 8vo. 3s. 6d.

WORKS BY T. M. GOODEVE, M.A.,

Barrister-at-Law, Professor of Mechanics at the Royal School of Mines.

PRINCIPLES of MECHANICS. New Edition, Re-written and Enlarged. With 253 Woodcuts and numerous Examples Crown 8vo. 6s.

The ELEMENTS of MECHANISM. New Edition, Re-written and Enlarged. With 342 Woodcuts. Crown 8vo. 6s.

A MANUAL of MECHANICS. An Elementary Text-book for Students of Applied Mechanics. With 138 Illustrations and Diagrams, and 141 Examples taken from the Science Department Examination Papers. With Answers. Fcap. 8vo. 2s. 6d.

Twelfth Edition, Revised and Enlarged, with 5 Coloured Plates and 923 Woodcuts. Crown 8vo. 15s.

GANOT'S TREATISE ON PHYSICS, Experimental and Applied, for the Use of Colleges and Schools. Translated and Edited from Ganot's "Éléments de Physique," by E. ATKINSON, Ph.D., F.C.S., Professor of Experimental Science, Staff College, Sandhurst.

Fifth Edition, with 20 Pages of New Matter, 2 Plates, and 495 Woodcuts. Crown 8vo. 7s. 6d.

GANOT'S NATURAL PHILOSOPHY, FOR GENERAL READERS AND YOUNG PERSONS. A Course of Physics divested of Mathematical Formulæ, expressed in the language of daily life. Translated and Edited from Ganot's "Cours Élémentaire de Physique," by E. ATKINSON, Ph.D., F.C.S., Professor of Experimental Science, Staff College, Sandhurst.

THE ELEMENTS OF CHEMISTRY. Theoretical and Practical. By W. ALLEN MILLER, M.D., LL.D.

PART I. Chemical Physics. Sixth Edition, Revised, with Additions, by H. MACLEOD, F.C.S. With 274 Woodcuts. 8vo. 16s.

PART II. Inorganic Chemistry. Sixth Edition, Revised throughout, with Additions by C. E. GROVES With 370 Woodcuts. 8vo. 24s.

PART III. The Chemistry of Carbon Compounds, or Organic Chemistry. With 20 Woodcuts. Fifth Edition. Revised, and for the most part Re-written, by H. E. ARMSTRONG, Ph.D., and C. E. GROVES, F.C.S. 8vo. 31s. 6d.

SELECT METHODS IN CHEMICAL ANALYSIS, chiefly Inorganic. By WILLIAM CROOKES, F.R.S., &c. Second Edition, Re-written and greatly Enlarged With 37 Woodcuts 8vo 24s.

A MANUAL OF PRACTICAL ASSAYING. By JOHN MITCHELL, F.C.S. Revised, with the Recent Discoveries incorporated, by W. CROOKES, F.R.S. 8vo. Woodcuts. 31s. 6d.

HOURS WITH A THREE-INCH TELESCOPE. By Capt. W. NOBLE, F.R.A.S., &c. With a Map of the Moon and 103 Woodcuts Crown 8vo. 4s. 6d.

A HAND-BOOK OF PRACTICAL TELEGRAPHY. By R. S. CULLEY, Member Inst.C.E., late Engineer-in-Chief of Telegraphs to the Post Office. Eighth Edition, Completely Revised. With 135 Woodcuts and 17 Plates. 8vo. 16s.

THE MARINE STEAM-ENGINE: a Treatise for the Use of Engineering Students and Officers of the Royal Navy. By R. SENNETT, R.N., Chief Inspector of Machinery, Admiralty With 261 Illustrations. 8vo. 21s.

THE GAS-ENGINE. By DUGALD CLERK. With 101 Illustrations and Diagrams. Crown 8vo. 7s. 6d.

THE STEAM-ENGINE. By GEORGE C. V. HOLMES, Whitworth Scholar, Secretary of the Institution of Naval Architects, Corresponding Member of the Society of Natural Sciences at Cherbourg, &c. Revised throughout by Prof JAMES STUART, M.P. With Frontispiece and 212 Illustrations and Diagrams. Fcap. 8vo. 6s.

London: LONGMANS, GREEN, AND CO.

NEW WORK BY PROFESSOR MILNES MARSHALL.

Ready This Day, with Numerous Illustrations, Crown 8vo, 10s. 6d.

A JUNIOR COURSE OF PRACTICAL ZOOLOGY.

By A. MILNES MARSHALL, M.D., D.Sc., M.A., F.R.S.,

Professor in the Victoria University; Beyer Professor of Zoology in Owens College; late Fellow of St. John's College, Cambridge.

Assisted by C. HERBERT HURST, Demonstrator and Assistant Lecturer in Zoology, Owens College, Manchester.

Diary of Societies.

LONDON

THURSDAY, FEBRUARY 17.

ROYAL SOCIETY, at 4.30.—A Record of Experiments upon the Functions of the Cerebral Cortex : Prof. Horsley, F.R.S., and Prof. Schäfer, F.R.S. —On Radiant Matter Spectroscopy; Examination of the Residual Glow : W. Crookes, F.R.S.

LINNEAN SOCIETY, at 8.—Phytobiological Observations Part II. Forms of Seedlings and Leaf of Liriodendron: Sir John Lubbock.—On Dichelaspis pellucida from Scales of Hydrophid : P. C. Hoek.—Observations on the Genus Ficus : Geo. King.

CHEMICAL SOCIETY, at 8.—Influence of Temperature on the Heat of Dissolutions of Salts : S. U. Pickering.—Researches on the Laws of Substitution in the Naphthalene Series; Dr. H. E. Armstrong.—Periodates : C. W. Kimmins, M.A., D.Sc.—On the Relation of Diazobenzeneanilide to Amidoazobenzene : R. F. Friswell and A. G. Green.

ROYAL INSTITUTION, at 3.—Molecular Forces. Prof. A. W. Rucker, F.R.S.

LONDON INSTITUTION, at 6.—Electric Bells, II. : Prof. Silvanus Thompson, Ph.D.

PARKES MUSEUM, at 5.—Food Adulteration and Analysis : Charles E. Cassal.

FRIDAY, FEBRUARY 18.

GEOLOGICAL SOCIETY, at 1.—Anniversary Meeting.

INSTITUTION OF CIVIL ENGINEERS, at 7.30.—Diving ; the Apparatus used, and the Work carried out under Water : Geo A. Becks.

ROYAL INSTITUTION, at 9.—Genesis of Elements : William Crookes, F.R.S.

SATURDAY, FEBRUARY 19.

ROYAL INSTITUTION, at 3.—Modern Composers of Classical Song—Jensen, Lassen, Holstein, Berlioz, and Wagner (with Vocal Illustrations) : Carl Armbruster.

SUNDAY, FEBRUARY 20.

SUNDAY LECTURE SOCIETY, at 4.—The Birth and Growth of Worlds : Prof. A. H. Green, F.R.S.

MONDAY, FEBRUARY 21.

VICTORIA INSTITUTE, at 8.—Caves, their Age, Origin, and Age of Deposit : Prof T. McK. Hughes.

LONDON INSTITUTION, at 5.—William the Silent : R. F. Horton.

TUESDAY, FEBRUARY 22.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—The Functional Topography of the Brain : Prof. Ferrier, F.R.S.—Description of the Cerebral Hemispheres of an Adult Australian Male : H. D. Rolleston.—On a Fossil Human Skull from Lagoa Santa, Brazil : Sören Hansen.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Irrigation in Lower Egypt : Wm Willcocks.

PHOTOGRAPHIC SOCIETY, at 8.

WEDNESDAY, FEBRUARY 23.

GEOLOGICAL SOCIETY, at 8.—On the Origin of Dry Chalk Valleys and of Coombe Rock. Clement Reid.—Quartzite Boulders and Grooves in the Roger Mine of Dukinfield : James Radcliffe.—Probable Amount of former Glaciation of Norway, as demonstrated by the present condition of Rocks upon and near the Western Coast : F. W. Stanley.

THURSDAY, FEBRUARY 24.

ROYAL SOCIETY, at 4.30.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS, at 8.—Telephonic Investigations : Prof. Silvanus P. Thompson. (Conclusion of Discussion.)

ATHENÆUM SOCIETY, at 8.

LONDON INSTITUTION, at 6.—The Lighthouse Experiments at the South Foreland : Harold B. Dixon, F.R.S.

SATURDAY, FEBRUARY 26.

PHYSICAL SOCIETY, at 3.—Note on Prof. Carey Foster's Method of Measuring the Mutual Induction of Two Coils : James Swinburne.

W. F. STANLEY

Mathematical Instrument Manufacturer to H.M. Government, Council of India, Science and Art Department, Admiralty, &c.

Mathematical, Drawing, and Surveying Instruments of Every Description.

FRY'S PURE
CONCENTRATED
SOLUBLE **COCOA**

Prepared by a new and special scientific process Securing extreme solubility, and developing the finest flavour of the Cocoa.

Excellent Copies of the **actual, natural Handwriting,** also of **Drawings, Music,** even of **elaborate Sketches, Programmes, Plans** (up to Double-Elephant size), **Shorthand,** and **Type-Writing** are easily, quickly, and cheaply produced by the

AUTOCOPYIST

Very fluid ink, used with ordinary pen and paper. Auto-Circulars resemble *written* letters. Used at the House of Lords &c.

AUTOCOPYIST CO.,
72 London Wall, London, and 52 Princess Street, Manchester.

VAN HOUTEN'S
pure soluble **COCOA**

is the best and, although a little dearer, really the cheapest in the end.

The *British Medical Journal* says:—"'VAN HOUTEN'S COCOA" is admirable. In flavour it is perfect, and it is so pure, well prepared, and rich," &c., &c.

HOLLOWAY'S OINTMENT

AN INFALLIBLE REMEDY

For **BAD LEGS, BAD BREASTS, OLD WOUNDS, SORES** and **ULCERS.** If effectually rubbed on the **Neck** and **Chest,** it cures **SORE THROATS, BRONCHITIS, COUGHS** and **COLDS;** and for **GOUT, RHEUMATISM,** and all **Skin Diseases** it is unequalled.

A NEW BOOK BY MR. J. NORMAN LOCKYER.

THE CHEMISTRY OF THE SUN.

BY J. NORMAN LOCKYER, F.R.S.,

Correspondant of the Institute of France, Foreign Member of the Academy of the Lyncei of Rome, &c., &c., &c.

With Illustrations, Demy 8vo, 14*s.*

The *Times* says:—

"The phrase (the chemistry of the sun) would have had no meaning half a century ago, and the results achieved, as described in Mr. Lockyer's clear, emphatic, and unconventional style, must far exceed the most sanguine dreams of early spectroscopists. They certainly scatter many of the fine fancies which the poets have woven round the face of our 'spotless' luminary; but have given us in their place facts which no poet could ever have approached in his wildest imaginings. . . . . Mr. Lockyer begins at the beginning, and traces carefully and with clear deliberation the progress of solar spectroscopy from the time of Kepler to the present day. . . . . We have only been able in the most summary manner to refer to some of the points of interest in this new volume, the numerous illustrations in which deserve a word of praise."

The *Academy* says:—

"The splendid work embodied in this treatise demands ample recognition at the hands of a reviewer. . . . Mr. Norman Lockyer has conferred a great boon upon chemists, physicists, and astronomers by gathering into one connected whole the chief results of the researches which have been made on the chemistry of the sun. He freely acknowledges the labours of other workers, although his own share in these difficult inquiries has been indeed ample. The illustrative woodcuts of apparatus, spectra, and solar phenomena, as well as the numerous tables of measurements, form an important feature of the volume. Whatever judgment may be formed as to the validity of his hypothesis, the indefatigable ardour with which he has attacked the great problem of the constitution of the sun, and the skill with which he has devised fresh methods of testing and re-testing the meaning of the phenomena observed and the soundness of the arguments based thereon, merit the warmest acknowledgment."

Optical and Dissolving View Lanterns.

WATSON & SONS' LANTERN LENS is unsurpassed by anything yet made for the purpose; it gives a sharpness of definition, flatness of field, and brilliancy of picture, hitherto unequalled. It has Rack Adjustment to Focus, and can be adapted to ANY LANTERN, Price **£1 10 0.**

WATSON & SONS' PARAFFIN LANTERN, fitted with Lens mentioned above, of the very finest quality throughout, with 4-inch Condensers, 4-Wick Refulgent Lamp, Mahogany Body, very suitable for School Exhibition or Home use, and exceedingly simple to work; in Portable Case, complete, **£6 6 0.**

LANTERN, exactly similar in all respects to above, but with Tin instead of Mahogany Body, **£4 10 0.**

WATSON & SONS' BIUNIAL AND TRIPLE LANTERNS, the highest quality Instruments made. Prices from—

	£	s.	d.
BIUNIAL	£7	10	0
TRIPLE	15	15	0

WATSONS' NEW SCREEN STAND, an immense convenience to Exhibitors; exceedingly light and compact to carry, easy to erect, perfectly rigid when set up, and holds the Screen tightly stretched. Price for 9-foot Screen, 35*s.*; 10-foot, 37*s.* 6*d.*; 12-foot, £2 2*s.* 0*d.*

An Illustrated Catalogue of Magic Lanterns and Apparatus, and List of large and varied Stock of Slides, post free on application.

WATSON & SONS' NEW HISTOLOGICAL MICROSCOPE.

AWARDED GOLD MEDAL, LIVERPOOL EXHIBITION, 1886.

FREE ON APPLICATION.

ILLUSTRATED CATALOGUE

OF

MICROSCOPES

AND

APPARATUS.

Classified List of 40,000 First-class Microscopic Objects.

A thoroughly first-rate Microscope at an extremely moderate price. It is mounted on an exceedingly firm brass foot, has sliding body for coarse adjustment, draw-tube, plane and concave mirrors, tube fitting of universal size for understage apparatus, with special arrangement for oblique illumination, set of diaphragms, with pin-hole stop, and is fitted with WATSON & SON'S improved form of fine adjustment, as supplied to their best instruments, which is perfectly free from all lateral motion, even when working with the highest powers, and permits of the greatest possible delicacy of adjustment. The entire instrument is finished in the very best manner, and is unequalled in value at the price.

Microscope as illustrated, with "C" eyepiece, ¼ and 1 inch first-class English objectives, giving a range of amplification from 75 to 700 diameters, in mahogany cabinet, price

£4 15s. 0d.

PHANTASMS OF THE LIVING.

By EDMUND GURNEY, M.A.,
Late Fellow of Trinity College, Cambridge;
FREDERIC W. H. MYERS, M.A.,
Late Fellow of Trinity College, Cambridge; and
FRANK PODMORE, M.A.

Published with the Sanction of the Council of the Society for Psychical Research.

Times: "The main purpose of these remarkable volumes is to break new ground in the region of psychical inquiry."

Spectator: "We cannot too heartily praise the sobriety of judgment with which the conclusions have been drawn. The book will long be regarded as the most serious attempt hitherto made to record the least explicable of psychical impressions, and to estimate their value."

Mind: "The massive result of an inquiry conducted with astonishing vigour and pertinacity."

St. James's Gazette: "Mr. Gurney tests the stories in a thoroughly sceptical spirit . . . The chain of reasoning is a strong one, and the amount and goodness of the evidence are startling. . . . The book is cleverly and brightly written."

Pall Mall Gazette: "Useful and arduous work diligently and ably done."

Daily Telegraph: "The treatise is full of interest and suggestion."

Science (Boston): "Untiring zeal in collecting facts, and patience in seeking to make them accurate; learning of the solidest sort in discussing them; in theorising, subtlety and originality, and, above all, fairness—for the work absolutely reeks with candour."

London: TRÜBNER & CO., Ludgate Hill.

pure soluble COCOA
is the best and, although a little dearer, really the cheapest in the end.

The *British Medical Journal* says:—"Van Houten's Cocoa" is admirable. In flavour it is perfect, and it is so pure, well prepared, and rich," &c., &c.

MACMILLAN'S MAGAZINE,
No. 329, for MARCH, Price 1s., contains—
1.—GENERAL LEE. By GENERAL VISCOUNT WOLSELEY.
2.—THE EARLIEST GREEK MORALIST.
3.—LYNCH LAW. By A. H. PATERSON.
4.—THE EVER-MEMORABLE JOHN HALES.
5.—A PSALM OF LIFE.
6.—SOME THOUGHTS ABOUT NOVELS.
7.—PERUGIA. By ARTHUR GALTON.
8.—THE SONG OF MALDON. By LT.-COLONEL LUMSDEN.
9.—THE LATE MASTER OF TRINITY. By the BISHOP OF CARLISLE.
10.—THE WOODLANDERS. Chapters XLI.—XLIII. By THOMAS HARDY.
MACMILLAN & CO., LONDON.

On the 1st of every Month, price Sixpence.
THE ENTOMOLOGIST:
AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOGY.
Edited by John T. Carrington,
With the Assistance of
Frederick Bond, F.Z.S. | Richard South.
Edward A. Fitch, F.L.S. | J. Jenner Weir, F.L.S.
F. Buchanan White, M.D.

Contains Articles by well-known Entomologists on all Branches of the Science; on Insects injurious or beneficial to Farm or Garden; Notes on Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthly Lists of Duplicates and Desiderata.

Woodcut Illustrations and occasional Lithographed and Chromo-Lithographed Plates.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

THE ZOOLOGIST:
A MONTHLY MAGAZINE OF NATURAL HISTORY.
Third Series. Edited by J. E. Harting, F.L.S., F.Z.S., Member of the British Ornithologists' Union; contains—

Original Articles by well-known naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds; occurrence of rare birds; distribution and migration of British fresh-water fish; new or rare marine fish; local aquaria; British reptiles; British land and fresh-water mollusca, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts.

JOHN VAN VOORST, 1 Paternoster Row.

HOLLOWAY'S PILLS THIS MEDICINE

Is a Certain Cure for all Disorders of the LIVER, STOMACH AND BOWELS. A Great PURIFIER of the BLOOD; a Powerful Invigorator of the System, in cases of WEAKNESS AND DEBILITY, and is unequalled in Female Complaints.

MESSRS. MACMILLAN & CO.'S SCIENTIFIC WORKS.

BIOLOGY.

A TEXT-BOOK OF PHYSIOLOGY. By MICHAEL FOSTER, M.D., Sec. R.S., Professor of Physiology in the University of Cambridge. With Illustrations. Fourth Edition, revised. 8vo. 21s.

ELEMENTARY PRACTICAL PHYSIOLOGY, A COURSE OF. By Prof. MICHAEL FOSTER, M.D., Sec. R.S., &c., and J. N. LANGLEY, M.A., F.R.S., Fellow of Trinity College, Cambridge. Fifth Edition. Crown 8vo. 7s. 6d.

PRIMER OF PHYSIOLOGY. By MICHAEL FOSTER, M.D., Sec. R.S., &c. With numerous Illustrations. 18mo. 1s. [*Science Primers.*

PHYSIOLOGY, ELEMENTARY LESSONS IN. By THOMAS HENRY HUXLEY, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d. (Questions on, 1s. 6d.)

ELEMENTS OF THE COMPARATIVE ANATOMY OF VERTEBRATES. Adapted from the German of ROBERT WIEDERSHEIM, Professor of Anatomy, and Director of the Institute of Human and Comparative Anatomy in the University of Friburg-in-Baden. By W. NEWTON PARKER, Professor of Biology in the University College of South Wales and Monmouthshire. With Additions by the Author and Translator. With Two Hundred and Seventy Woodcuts. Medium 8vo. 12s. 6d.

A TREATISE ON COMPARATIVE EMBRYOLOGY. By F. M. BALFOUR, M.A., F.R.S., Fellow and Lecturer of Trinity College, Cambridge. With Illustrations. Second Edition, reprinted without alteration from the First Edition. In 2 vols. 8vo. Vol. I 18s. Vol. II 21s.

THE ELEMENTS OF EMBRYOLOGY. By MICHAEL FOSTER, M.A., M.D., LL.D., Sec. R.S., Professor of Physiology in the University of Cambridge, Fellow of Trinity College, Cambridge, and the late FRANCIS M. BALFOUR, M.A., LL.D., F.R.S., Fellow of Trinity College, Cambridge, and Professor of Animal Morphology in the University. Second Edition, revised. Edited by ADAM SEDGWICK, M.A., Fellow and Assistant Lecturer of Trinity College, Cambridge, and WALTER HEAPE, Demonstrator in the Morphological Laboratory of the University of Cambridge. Illustrated. 10s. 6d.

ELEMENTS OF COMPARATIVE ANATOMY. By Professor CARL GEGENBAUR. A Translation by F. JEFFREY BELL, B.A. Revised with Preface by Professor E. RAY LANKESTER, F.R.S. With numerous Illustrations. 8vo. 21s.

ANATOMY, LESSONS IN ELEMENTARY. By ST. GEORGE MIVART, F.R.S. With numerous Illustrations. Fcap. 8vo. 6s 6d.

A TEXT-BOOK OF THE PHYSIOLOGICAL CHEMISTRY OF THE ANIMAL BODY. Including an Account of the Chemical Changes occurring in Disease. By A. GAMGEE, M.D., F.R.S., Professor of Physiology in the Victoria University, the Owens College, Manchester. 2 vols. 8vo. With Illustrations. Vol. I. 18s. [*Vol. II. in the press.*

A COURSE OF PRACTICAL INSTRUCTION IN ELEMENTARY BIOLOGY. By THOMAS HENRY HUXLEY, F.R.S., assisted by H. N. MARTIN, M.B., D.Sc. New Edition, revised. Crown 8vo 6s.

AN INTRODUCTION TO THE OSTEOLOGY OF THE MAMMALIA. By WILLIAM HENRY FLOWER, LL.D., F.R.S., Director of the Natural History Departments of the British Museum, late Hunterian Professor of Comparative Anatomy and Physiology in the Royal College of Surgeons of England. With numerous Illustrations. Third Edition: Revised with the assistance of HANS GADOW, Ph D., M.A., Lecturer on the Advanced Morphology of Vertebrates and Strickland Curator in Univ. of Camb Cr. 8vo. 10s. 6d.

AN ATLAS OF PRACTICAL ELEMENTARY BIOLOGY. By G. B. HOWES, Assistant Professor of Zoology. Normal School of Science and Royal School of Mines. With a Preface by THOMAS HENRY HUXLEY, F.R.S. Royal 4to. 14s.

A COURSE OF INSTRUCTION IN ZOOTOMY (VERTEBRATA). By T. JEFFREY PARKER, B Sc. London, Professor of Biology in the University of Otago, New Zealand. With Illustrations. Crown 8vo. 8s. 6d.

THE FERTILISATION OF FLOWERS. By Professor HERMANN MÜLLER. Translated and Edited by D'ARCY W. THOMPSON, B.A., Professor of Biology in University College, Dundee. With a Preface by CHARLES DARWIN, F.R.S. With numerous Illustrations. Medium 8vo. 21s.

BIOLOGY—*continued.*

STRUCTURAL BOTANY, OR ORGANOGRAPHY ON THE BASIS OF MORPHOLOGY. To which are added the Principles of Taxonomy and Phytography, and a Glossary of Botanical Terms. By Professor ASA GRAY, LL.D. 8vo. 10s. 6d.

PRACTICAL INSTRUCTION IN BOTANY, A COURSE OF. By F. O. BOWER, M.A., F.L.S., Professor of Botany in the University of Glasgow, and SYDNEY H. VINES, M.A., D.Sc., F.R.S., Fellow and Lecturer, Christ's College. Cambridge With a Preface by W. T. THISELTON DYER, M.A., C.M.G., F.R.S., F.L.S., Director of the Royal Gardens, Kew.

Part I.—PHANEROGAMÆ—PTERIDOPHYTA. Crown 8vo. 6s.

LESSONS IN ELEMENTARY BOTANY. By Professor OLIVER, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d.

PRIMER OF BOTANY. By Sir J. D. HOOKER, K.C.S.I., C.B., M.D., F.R.S., D.C.L. With numerous Illustrations. New Edition 18mo. 1s. [*Science Primers.*

THE STUDENT'S FLORA OF THE BRITISH ISLANDS. By Sir J. D. HOOKER, K.C.S.I., C.B., M.D., F.R.S., D.C.L. Third Edition, revised. Globe 8vo. 10s. 6d.

FIRST BOOK OF INDIAN BOTANY. By DANIEL OLIVER, F.R.S., &c., Professor of Botany in University College, London, &c. With Illustrations. Extra fcap. 8vo. 6s. 6d.

A DICTIONARY OF ECONOMIC PLANTS. Their History, Products, and Uses. By JOHN SMITH, A.L.S., &c. 8vo. 14s.

DOMESTIC BOTANY. An Exposition of the Structure and Classification of Plants, and their Uses for Food, Clothing, Medicine, and Manufacturing Purposes. By JOHN SMITH, A.L.S., &c. With Illustrations. New Issue. Crown 8vo. 12s. 6d.

EUROPEAN BUTTERFLIES, A HANDBOOK OF. By W. F. DE VISMES KANE, M.A., M.R.I.A., Member of the Entomological Society of London, &c. With Copper Plate Illustrations. Crown 8vo. 10s. 6d.

A LIST OF EUROPEAN RHOPALOCERA, WITH THEIR VARIETIES AND PRINCIPAL SYNONYMS Reprinted from the *Handbook of European Butterflies.* Crown 8vo. 1s.

ANTHROPOLOGY.

ANTHROPOLOGY. An Introduction to the Study of Man and Civilisation. By E. B. TYLOR, D.C.L., F.R.S. With numerous Illustrations. Crown 8vo. 7s. 6d.

MEDICINE.

A TEXT-BOOK OF PHARMACOLOGY, THERAPEUTICS, AND MATERIA MEDICA. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.C.P., F.R.S., Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; late Examiner in the University of Edinburgh. Adapted to the United States Pharmacopoeia, by FRANCIS H. WILLIAMS, M.D., Boston, Mass. Second Edition. Adapted to the New British Pharmacopoeia, 1885. Medium 8vo. 21s

TABLES OF MATERIA MEDICA: a Companion to the Materia Medica Museum. By the same Author. With Illustrations. New Edition Enlarged. 8vo. 10s. 6d.

TEXT-BOOK OF PATHOLOGICAL ANATOMY AND PATHOGENESIS. By Prof. ERNST ZIEGLER of Tubingen. Translated and Edited for English Students by DONALD MACALISTER, M.A., M.D., B.Sc., F.R.C.P., Fellow and Medical Lecturer of St John's College, Cambridge, Physician to Addenbrooke's Hospital, and Teacher of Medicine in the University. With numerous Illustrations. Medium 8vo.

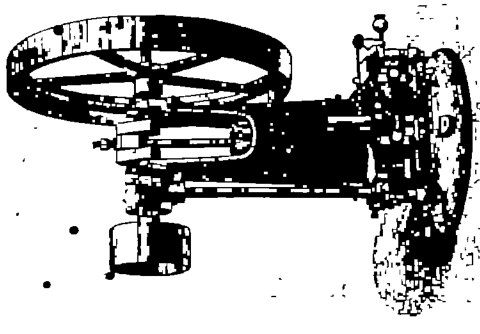
Part I.—GENERAL PATHOLOGICAL ANATOMY. Second Edition. 12s. 6d.

Part II.—SPECIAL PATHOLOGICAL ANATOMY. Sections I.—VIII. Second Edition. 12s 6d. Sections IX.—XII. 12s. 6d.

MICRO-ORGANISMS AND DISEASE. An Introduction into the Study of Specific Micro-Organisms. By E. KLEIN, M.D., F.R.S., Lecturer on General Anatomy and Physiology in the Medical School of St. Bartholomew's Hospital, London. With 121 Illustrations. Third Edition. Revised. Crown 8vo. 6s.

MACMILLAN & CO., LONDON.

THE
"OTTO"
GAS-ENGINE.
OVER 20,000 SOLD.



CROSSLEY'S
NEW 5-MAN POWER
"OTTO"
GIVES OFF 1 H.P. ON THE BRAKE.

Very suitable for driving amateurs' workshop, pumping water to house, driving laundry machinery, chaff-cutting, &c.

Can be supplied combined with pumps or with dynamo (for electric lighting (the dynamo & pump being disconnected when engine is required for other purposes).

CROSSLEY BROS.,
Limited,
MANCHESTER.

A NEW BOOK BY MR. J. NORMAN LOCKYER.

THE CHEMISTRY OF THE SUN.

BY J. NORMAN LOCKYER, F.R.S.,

Correspondant of the Institute of France, Foreign Member of the Academy of the Lyncei of Rome, &c., &c., &c.

With Illustrations, Demy 8vo, 14*s*.

The *Times* says:—

"The phrase (the chemistry of the sun) would have had no meaning half a century ago, and the results achieved, as described in Mr. Lockyer's clear, emphatic, and unconventional style, must far exceed the most sanguine dreams of early spectroscopists. They certainly scatter many of the fine fancies which the poets have woven round the face of our 'spotless' luminary; but have given us in their place facts which no poet could ever have approached in his wildest imaginings. . . . . Mr. Lockyer begins at the beginning, and traces carefully and with clear deliberation the progress of solar spectroscopy from the time of Kepler to the present day. . . . . We have only been able in the most summary manner to refer to some of the points of interest in this new volume, the numerous illustrations in which deserve a word of praise."

The *Academy* says:—

"The splendid work embodied in this treatise demands ample recognition at the hands of a reviewer. . . . Mr. Norman Lockyer has conferred a great boon upon chemists, physicists, and astronomers by gathering into one connected whole the chief results of the researches which have been made on the chemistry of the sun. He freely acknowledges the labours of other workers, although his own share in these difficult inquiries has been indeed ample. The illustrative woodcuts of apparatus, spectra, and solar phenomena, as well as the numerous tables of measurements, form an important feature of the volume. Whatever judgment may be formed as to the validity of his hypothesis, the indefatigable ardour with which he has attacked the great problem of the constitution of the sun, and the skill with which he has devised fresh methods of testing and re-testing the meaning of the phenomena observed and the soundness of the arguments based thereon, merit the warmest acknowledgment."

The *Scotsman* says:—

"No man in this country can surpass Mr. Lockyer in the rare combination of painstaking accuracy in experimental work, sterling impartiality of judgment, and brilliant clearness in the expression of his opinions. His numerous published works have assigned him the highest place as an authority on solar physics. . . . . The author's work is to be highly commended; whatever conclusions scientific critics may arrive at as to the value of the hypothesis so ably advocated, there can be no two opinions about the uniform modesty and courteous respect for others which breathe through every page of the volume; the brilliant but clear style of the language in which his thoughts are clothed; the exemplary enthusiasm by which he carries his readers on over much which otherwise would be hard and dry; and the genuine scientific scholarship which never courts the tactics of the mountebank."

MACMILLAN & CO., LONDON.

Third Edition in a few days.

ADAPTED TO THE NEW BRITISH PHARMACOPŒIA, 1885.

Medium 8vo, price 21*s*.

A TEXT-BOOK OF PHARMACOLOGY, THERAPEUTICS, and MATERIA MEDICA.

By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S., Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; Late Examiner in the University of Edinburgh.

ADAPTED TO THE UNITED STATES PHARMACOPŒIA BY F. H. WILLIAMS, M.D., BOSTON, MASS.

"The work has little in common with the old-fashioned books on materia medica. . . . It is not a mere collection of dry facts and technical details, but a scientific treatise worthy to be ranked with the highest productions in physiology, either in our own or any other language. . . . It is a book of study for the scientist and a work of reference for the practical physician."—*Lancet*.

BY THE SAME AUTHOR.

DISORDERS OF DIGESTION: THEIR CONSEQUENCES AND TREATMENT.

This Work contains, in addition to the Lettsomian Lectures, a number of other Papers by the Author on similar subjects.

8vo, 10*s*. 6*d*.

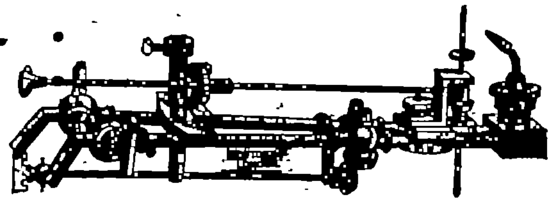
GOLD MEDAL,
International Inventions Exhibition, 1885.

NEW PATTERN OXY-HYDROGEN JET
FOR LIME-LIGHT LANTERN.



This jet, designed by LEWIS WRIGHT, Esq., gives a *most powerful light*, with a minimum of trouble. The lime-pin, of Bessemer steel, has a deep spiral cut in it, to which Newton's new check-action is fitted. By this arrangement, the whole lime-surface is used, yet the light never impinges twice on the same spot.

A new "cut-off," devised by ANDREW PRINGLE, Esq., is also fitted to these jets, by which the light can be turned up or down without altering the taps.

Can be seen at work at 3 Fleet Street.

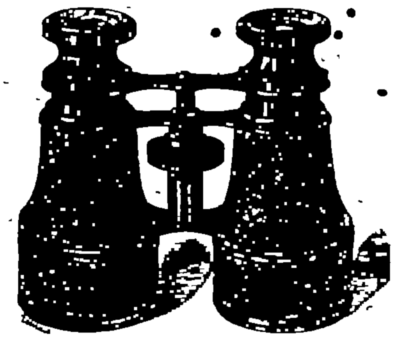
Price, best workmanship, 47*s.* 6*d.*, as supplied to A. PRINGLE, Esq., who writes:—

"I write to let you know of the great success of the jet you made for me; it gives a grand light, and does not crack the limes as most jets do. Regarding the cut-off, every time I use it I like it better."

Price, without "cut-off" (as supplied to L. WRIGHT, Esq.), 32*s.* 6*d.*

NEWTON & CO., 3 Fleet Street, London, E.C.

BROWNING'S BINOCULARS.



THE "ECONOMICAL" FIELD-GLASS.

This Binocular has achromatic object-glasses 1¼ inch in diameter, and sliding shades to shelter the object-glasses from sun or rain, and is fitted in a solid leather sling case, price £1 5*s.*; sent free

Illustrated Catalogue of Binoculars post free.

Medicine.		
Two in Medicine	150*l.*	Vacant. Vacant.
Two in Surgery	150*l.*	W. Morrant Baker, Esq. Prof. Christopher Heath.
Two in Anatomy	100*l.*	Prof. D. J. Cunningham, M.D., C.M. Prof. John Curnow, M.D.
Two in Physiology	100*l.*	Prof. E. A. Schafer, F.R.S. Prof. Gerald F. Yeo, M.D.
Two in Obstetric Medicine	75*l.*	F. H. Champneys, Esq., M.A., M.D. John Williams, Esq., M.D.
Two in Materia Medica and Pharmaceutical Chemistry	75*l.*	J. Mitchell Bruce, Esq., M.D., M.A. T. Lauder Brunton, Esq., M.D., F.R.S.
Two in Forensic Medicine	50*l.*	Thomas Stevenson, Esq., M.D. Vacant.
Music		
Two in Music	50*l.*	William Pole, Esq., Mus.Doc., F.R.S. John Stainer, Esq., Mus.Doc., M.A.

The Examiners above named are re-eligible, and intend to offer themselves for re-election.

Candidates must send in their names to the Registrar, with any attestation of their qualifications they may think desirable, on or before Tuesday, March 29. It is particularly desired by the Senate that no personal application of any kind be made to its individual Members.

By order of the Senate,

ARTHUR MILMAN, M.A.,
Registrar.

University of London,
Burlington Gardens, W.,
March 1, 1887.

A FRENCH GENTLEMAN, with First-rate Scholastic Recommendations, has a French Class for Army Pupils at 2 Colville Gardens, Bayswater. He and his wife also receive as Boarders two or three Young Men who wish to study the language for business or conversational purposes.—Address M. ALFRED VIVIER, Swanley, Kent.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to

THOMAS BOLTON, 57 NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers Larval form of the Acorn Barnacle, Balanus balanoides, in the Nauplius stage, with drawing and description. He also sent out Salmon Fry, Grayling Ova, Lophopus crystallinus, Paludicella Ehrenbergi, Argulus foliaceus, Entomostraca, Melicerta ringens, various swimming Rotifers, Spongilla fluviatilis, Volvox globator, Desmids, also Hydra, Amœba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s., or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

OWENS COLLEGE, MANCHESTER.

The SENATE invite applications for the post of SENIOR DEMONSTRATOR in PHYSIOLOGY. The Stipend will be £150 per annum. A detailed statement of the duties, &c., may be obtained from the Registrar.

Applications with Testimonials should be addressed to the Senate under cover to the REGISTRAR, not later than March 21.

HENRY WM. HOLDER, M.A., Registrar.

SCHOOL BOARD FOR LONDON.

The School Board for London are about to appoint Three SCIENCE DEMONSTRATORS, who will be required to visit Schools under the direction of the Board for the purpose of giving instruction in Mechanics.

The persons appointed will be required to devote the whole of their time to the work of the Board, and the appointments will be for three years.

Salary 175*l.* per annum, rising by annual increases of 5*l.*, with an allowance of a sum not exceeding 75*l.* per annum for personal travelling expenses, the conveyance from school to school of the apparatus required in the demonstrations, and for assistance in the experiments.

Applications, together with copies of not more than three Testimonials, must be sent so as to reach the Clerk of the Board, School Board for London, Victoria Embankment, W.C., on or before Saturday, March 12, marked outside "Science Demonstrator."

VICTORIA (PHILOSOPHICAL) INSTITUTE.

MEETING MONDAY, MARCH 7. Paper on "ORIENTAL ENTOMOLOGY."
By Rev. F. A. WALKER, D.D., F.L.S.

House of Institute, 7 Adelphi Terrace, Charing Cross.

The above is a Society of (at present 1200) English and Foreign Men of Science and Authors (and others desiring the privileges of Membership) for the purpose of investigating fully and impartially important questions of Philosophy and Science.

Next days for Election of Members, March 7 and March 21.

NORMAL SCHOOL OF SCIENCE.—A Gentleman studying will find a quiet and refined Home in the house of a Lady. Moderate terms. References to parents.—Mrs. KEBLE, 42 Tregunter Road, South Kensington (Earl's Court Station).

BERKHAMPSTED SCHOOL, HERTS. Twenty-eight miles from Euston. Good Scholarships and Exhibitions. Laboratory, heated swimming-bath, workshop, &c. £52 per annum.—Address, Head-Master.

BIOLOGY AND PHYSICS.—Coaching for Prelim. Sci. and B.Sc. by former Demonstrator. Over 50 Successes.—G. WILLIAM HILL, M.B., B.Sc. Lond., 37 Cornwall Road, W.

BOOKS (Secondhand), Miscellaneous, Re-mainders, &c.—C. HERBERT, English and Foreign Bookseller, 319 Goswell Road, London, E.C. Catalogue free on receipt of two stamps. Libraries, Old Books, and Parchments purchased.

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1s. per bottle, with full instructions for use, from most Opticians. Post free for 1s. 3d. from

RECENT VOLUMES IN
THE INTERNATIONAL SCIENTIFIC SERIES.
With 38 Figures, 5s.
EARTHQUAKES AND OTHER EARTH MOVEMENTS By JOHN MILNE, Professor of Mining and Geology in the Imperial College of Engineering, Tokio.
"Masterly and interesting volume"—*Saturday Review.*
"The book is the high-water mark of modern science in its investigation of the origin and course of phenomena."—*Pall Mall Gazette.*
"The work is well worthy of its place in the International Scientific Series, and may be accepted as a monograph on its subject by an accomplished seismologist."—*Nature.*
With 107 Illustrations, 5s.
MICROBES, FERMENTS, and MOULDS. By E. L. TROUESSART.
"The volume is a complete repertoire of facts and theories relating to the subject of germ-life."—*Nature*
"The book supplies very well a long-felt want, and will worthily fill a gap in scientific libraries."—*Spectator.*
Crown 8vo, with Frontispiece, 5s.
THE GEOGRAPHICAL AND GEOLOGICAL DISTRIBUTION OF ANIMALS. By ANGELO HEILPRIN, Professor of Invertebrate Palæontology at the Academy of Natural Sciences at Philadelphia.
London: KEGAN PAUL, TRENCH, & CO.

Now Ready, Fifth Edition, with 1178 Engravings, Crown 8vo, 15s
A MANUAL OF BOTANY, including the Structure, Classification, Properties, Uses, and Functions of Plants. By ROBERT BENTLEY, Professor of Botany in King's College, London, and to the Pharmaceutical Society.
London: J. & A. CHURCHILL, 11 New Burlington Street.

FOWNES-WATTS' CHEMISTRY.
PHYSICAL AND INORGANIC CHEMISTRY. By HENRY WATTS, B.A., F.R.S., Author of "A Dictionary of Chemistry," &c With Coloured Plate of Spectra and 150 Wood Engravings, Crown 8vo, 9s.
CHEMISTRY of CARBON COMPOUNDS; or, ORGANIC CHEMISTRY. By HENRY WATTS, B.A., F.R.S. Edited by WILLIAM A. TILDEN, D.Sc., F.R.S., Professor of Chemistry in the Mason College, Birmingham. Second Edition. With Engravings, Crown 8vo, 10s.
*** These two volumes are based on the well-known Manual of the late Prof Fownes, and form the Thirteenth Edition of that work.
London. J. & A CHURCHILL, 11 New Burlington Street.

Now Ready. 8vo, 6s
ELEMENTARY PRACTICAL BIOLOGY—VEGETABLE. By THOMAS W. SHORE, M.D., B.Sc. (Lond.), Lecturer on Comparative Anatomy at St. Bartholomew's Hospital.
London: J. & A. CHURCHILL, 11 New Burlington Street.

MUSEUMS AND COLLECTORS.
MR. DAMON, of WEYMOUTH, will forward an abridged Catalogue of his Collections in Natural History Objects, including RECENT SHELLS (Foreign and British), FOSSIL REMAINS, MINERALS, ROCKS, MARINE ZOOLOGY, &c., &c., &c.

SIX PRIZE MEDALS
AWARDED FOR GEOLOGICAL COLLECTIONS.
Geological Collection especially adapted for Teaching as supplied to Science and Art Department, and used by all Lecturers and Teachers in Great Britain, &c.
New and Rare Minerals constantly arriving from all parts for selection of Single Specimens.
ROCK SECTIONS AND ROCK SPECIMENS:
The Largest Variety in England.

J. & A. CHURCHILL.

Now Ready, Price 7s. 6d.

PRACTICAL ELECTRICITY.

A Laboratory and Lecture Course, for First-Year Students of Electrical Engineering, based on the Practical Definitions of the Electrical Units.

BY W. E. AYRTON, F.R.S.,

Assoc. Mem. Inst. C.E., Professor of Applied Physics at the City and Guilds of London Central Institution. With Numerous Illustrations.

This book is intended to assist students in acquiring experimentally an *exact* working knowledge of electric current, difference of potentials, resistance, electromotive force, quantity, capacity, and power. It does not merely contain short instructions for the carrying out of experiments such as may be found in existing books on practical physics, nor, on the other hand, does it resemble certain text-books, mainly of value as electrical dictionaries, which give a little information about everything that can be comprised under the head of electricity, whether it be electric eels, the history of the invention of the telegraph, the aurora, or the earliest forms of frictional machines.

CASSELL & COMPANY, LIMITED, Ludgate Hill, London.

In One Vol. Royal 8vo, Cloth, New Edition (Third), Price 31s. 6d.

CANAL AND RIVER ENGINEERING.

BY DAVID STEVENSON,

F.R.S.E., Late Member of the Institution of Civil Engineers.

New Edition (Third)

BY D. A. STEVENSON, B.Sc., F.R.S.E., and C. A. STEVENSON, B.Sc., Civil Engineer. Profusely Illustrated.

Edinburgh: A. & C. BLACK. London: LONGMANS.

W. F. STANLEY

Mathematical Instrument Manufacturer to H.M. Government, Council of India, Science and Art Department, Admiralty, &c.

Mathematical, Drawing, and Surveying Instruments of Every Description.

W. F. S. obtained the only Medal in the Great Exhibition of 1862 for Excellence of Construction of Mathematical Instruments, and the only GOLD MEDAL in the International Inventions Exhibition 1885 for Mathematical Work. Silver Medal, Architects' Exhibition, 1886.

Address:—GREAT TURNSTILE, HOLBORN, LONDON, W.C.

Diary of Societies.

LONDON.

THURSDAY, MARCH 3.

ROYAL SOCIETY, at 4.30.—Preliminary Note on a Balanoglossus Larva from the Bahamas: W. F. R. Weldon.—Studies on some New Micro-organisms obtained from Air: G. C. and Dr. P. Frankland.—On the Limiting Distance of Speech by Telephone: W. H. Preece, F.R.S.—The Etiology of Scarlet Fever: Dr. Klein, F.R.S.

LINNEAN SOCIETY, at 8.—Genetic Affinities and Classification of Algæ: Alfred W. Bennett.—Fungoid Disease of Colocasia in Jamaica: G. Massee and D. Morris.

CHEMICAL SOCIETY, at 8.—Ballot for the Election of Fellows.—The Colouring-Matter of Drosera Whittakeri: Prof. Rennie.—Anhydracetonebenzil: F. R. Japp and C. F. Burton.—Condensation of Benzil with Ketones: F. R. Japp and C. F. Burton.—The Constitution of Glycosine: F. R. Japp and E. Clemenshaw.—Diphenylglyoxaline and its Homologues: F. R. Japp.—Dehydracetic Acid: Dr. W. H. Perkin, Jun.

ROYAL INSTITUTION, at 3.—The Critics of the Age of Anne: Edmund Gosse.

LONDON INSTITUTION, at 7.—Musical Instruments: John Radcliffe.

FRIDAY, MARCH 4.

GEOLOGISTS' ASSOCIATION, at 8.—A Revision of our Lower Eocenes: G. F. Harris.

SOCIETY OF ARTS, at 8.—Our Trade Route to the East: Major-General Sir F. J. Goldsmid, K.C.S.I., C.B.

INSTITUTION OF CIVIL ENGINEERS, at 7.30.—Propelling Machinery of Modern War-Ships: Sydney H. Wells.

ROYAL INSTITUTION, at 9.—Brain Surgery in the Stone Ages: Victor Horsley, F.R.S.

SATURDAY, MARCH 5.

ROYAL INSTITUTION, at 3.—Sound: Lord Rayleigh, F.R.S.

SUNDAY, MARCH 6.

SUNDAY LECTURE SOCIETY, at 4.—The Probable Origin and Spread of Life: George Massee. (Illustrated by Diagrams.)

MONDAY, MARCH 7.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—M. Hermite's System of Electrolytic Bleaching:—Messrs. Cross and Bevan.—(1) Castner's Sodium Process; (2) A New Method of Elevating Liquids Specially Applicable to Acids: Jas. Mactear.

SOCIETY OF ARTS, at 8.—Building Materials: W. Y. Dent.

VICTORIA INSTITUTE, at 8.—Oriental Entomology: Rev. F. A. Walker.

ODONTOLOGICAL SOCIETY, at 8.

ROYAL INSTITUTION, at 5.—General Monthly Meeting.

LONDON INSTITUTION, at 5.—Life in Homer's Days: Andrew Lang.

TUESDAY, MARCH 8.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—Stone Circles near Aberdeen: A. L. Lewis.—Palæolithic Implements from the Drift Gravels of the Singrauli Basin, South Mirzapore: J. Cockburn.—Stone Implements from Perak: Abraham Hale.

INSTITUTION OF CIVIL ENGINEERS, at 8.

ROYAL INSTITUTION, at 3.—The Function of Respiration: Prof. Arthur Gamgee, F.R.S.

WEDNESDAY, MARCH 9.

GEOLOGICAL SOCIETY, at 8.—On Chondrosteus acipenseroides, Agassiz: James W. Davis.—On Aristosuchus pusillus, Ow., being further Notes on the Fossils described by Sir R. Owen as Poikilopleuron pusillus, Ow.: Prof. H. G. Seeley, F.R.S.—On Patricosaurus merocratus, Seeley, a Lizard from the Cambridge Greensand, preserved in the Woodwardian Museum of the University of Cambridge: Prof. H. G. Seeley, F.R.S.—On Heterosuchus valdensis, Seeley, a procœlian Crocodile from the Hastings Sands of Hastings: Prof. H. G. Seeley, F.R.S.—On a Sacrum, apparently indicating a New Type of Bird (Ornithodesmus pygidius, Seeley) from the Wealden of Brook: Prof. H. G. Seeley, F.R.S.

ROYAL MICROSCOPICAL SOCIETY, at 8.—On the Differentiation of Tissues in Fungi: G. Massee.—On Section-Cutting of Sponges and other similar Structures with Soft and Hard Tissues: Dr. H. J. Johnston-Lavis and Dr. G. C. J. Vosmaer.

SOCIETY OF ARTS, at 8.—Railway Brakes: William P. Marshall.

THURSDAY, MARCH 10.

ROYAL SOCIETY, at 4.30.—The following Papers will probably be read:—(1) Note on Induction-Coils or "Transformers"; (2) Note on the Theory of the Alternate Current Dynamo: Dr. J. Hopkinson, F.R.S.—Transmission of Sunlight through the Earth's Atmosphere: Capt. Abney, F.R.S.

MATHEMATICAL SOCIETY, at 8.—On Elimination and on a Metrical Property of Plane Curves: R. Lachlan.—Note on the Weierstrass Functions: A. G. Greenhill.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS, at 8.—Reversible Lead Batteries and their Use for Electric Lighting: Desmond G. FitzGerald.

ATHENÆUM SOCIETY, at 8.—Anniversary.

ROYAL INSTITUTION, at 3.—The Critics of the Age of Anne: Edmund Gosse.

LONDON INSTITUTION, at 7.—The most Celebrated Composers for the Piano since 1830: Prof. Ernst Pauer.

FRIDAY, MARCH 11.

ROYAL ASTRONOMICAL SOCIETY, at 8.

ROYAL INSTITUTION, at 9.—Society in the Fourth Century A.D.: Ven. Archdeacon Farrar, F.R.S.

SATURDAY, MARCH 12.

ROYAL INSTITUTION, at 3.—Sound: Lord Rayleigh, F.R.S.

PHYSICAL SOCIETY, at 3.

OFFICE OF "NATURE," 29, BEDFORD STREET, STRAND.

A NEW BOOK BY MR. J. NORMAN LOCKYER.

THE CHEMISTRY OF THE SUN.

BY J. NORMAN LOCKYER, F.R.S.,

Correspondant of the Institute of France, Foreign Member of the Academy of the Lyncei of Rome, &c., &c., &c.

With Illustrations, Demy 8vo, 14*s.*

The *Times* says:—

"The phrase (the chemistry of the sun) would have had no meaning half a century ago, and the results achieved, as described in Mr. Lockyer's clear, emphatic, and unconventional style, must far exceed the most sanguine dreams of early spectroscopists. They certainly scatter many of the fine fancies which the poets have woven round the face of our 'spotless' luminary; but have given us in their place facts which no poet could ever have approached in his wildest imaginings. . . . Mr. Lockyer begins at the beginning, and traces carefully and with clear deliberation the progress of solar spectroscopy from the time of Kepler to the present day. . . . We have only been able in the most summary manner to refer to some of the points of interest in this new volume, the numerous illustrations in which deserve a word of praise."

Third Edition in a few days.

ADAPTED TO THE NEW BRITISH PHARMACOPŒIA, 1885.

Medium 8vo, price 21*s.*

A TEXT-BOOK OF PHARMACOLOGY, THERAPEUTICS, and MATERIA MEDICA.

By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S., Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; Late Examiner in the University of Edinburgh.

ADAPTED TO THE UNITED STATES PHARMACOPŒIA BY F. H. WILLIAMS, M.D., BOSTON, MASS.

"The work has little in common with the old-fashioned books on materia medica. . . . It is not a mere collection of dry facts and technical details, but a scientific treatise worthy to be ranked with the highest productions in physiology, either in our own or any other language. . . . It is a book of study for the scientist and a work of reference for the practical physician."—*Lancet.*

BY THE SAME AUTHOR.

DISORDERS OF DIGESTION: THEIR CONSEQUENCES AND TREATMENT.

This Work contains, in addition to the Lettsomian Lectures, a number of other Papers by the Author on similar subjects. 8vo, 10*s.* 6*d.*

"Distinguished by accurate observation and original thinking, these papers have been largely instrumental in moulding current medical opinion in regard to many of the subjects with which they are concerned."—*Edinburgh Medical Journal.*

"We can cordially recommend the volume, as one which combines much practical and technical information and sound common sense."—*London Medical Record.*

Cheaper Issue, 8vo, Price 3s. 6d.

ESSEX FIELD CLUB SPECIAL MEMOIRS, VOL. I.

REPORT ON THE EAST ANGLIAN EARTHQUAKE OF APRIL 22, 1884.

By RAPHAEL MELDOLA, F.C.S., F.I.C., F.R.A.S., &c., Professor of Chemistry in the Finsbury Technical College, City and Guilds of London Institute; and WILLIAM WHITE, F.E.S., Member of the Geologists' Association. Drawn up by R. MELDOLA, and read in Abstract at the Meeting of the Essex Field Club, February 28, 1885. With Maps and other Illustrations. Cheaper Issue, 8vo, 3*s.* 6*d.*

The *Athenæum* says:—"A distinctly valuable contribution to our knowledge of a subject of much obscurity. . . . The subject is one which only a few specialists will pursue within its narrower limits, but the curious facts collected, and the odd scraps of history referring to past earthquakes which have been gathered together are so numerous, so unexpected, and so well set, that the book will be found extremely interesting to the general reader, as well as a suggestive and severe study for the man of science.',

BY HENRY CALDERWOOD, LL.D.,

Professor of Moral Philosophy in the University of Edinburgh.

THE RELATIONS OF MIND AND BRAIN. Second Edition,

Revised and Enlarged, with an additional Chapter on Animal Intelligence. 8vo, 12*s.*

"Contains the suggestion of a principle which may prove to be capable of explaining much that is at present obscure in the relations between the mind and the body."—*Scotsman.*

"Professor Calderwood's 'Relations of Mind and Brain' is one of the most cautious, and at the same time exhaustive, treatises which we have on the subject."—*British Quarterly Review.*

"In the new chapter on Animal Intelligence, Dr. Calderwood does excellent service by bringing expressly into view the peculiarities of sense-endowment distinguishing the different classes of animals (ants, dogs, &c.) for which exceptional intelligence is claimed; and he is thus able to account for much in their action that is too readily regarded as mysterious."—*Mind.*

"As indispensable as Bradshaw."—*Times.*

TWENTY-FOURTH YEAR OF PUBLICATION (Revised after Official Returns) of the

STATESMAN'S YEAR-BOOK: a Statistical and Historical Annual of

the States of the Civilised World for the Year 1887. Edited by J. SCOTT KELTIE, Librarian to the Royal Geographical Society. Crown 8vo, 10*s.* 6*d.* [*Next week.*

GOLD MEDAL,
International Inventions Exhibition, 1885.

Now Ready,

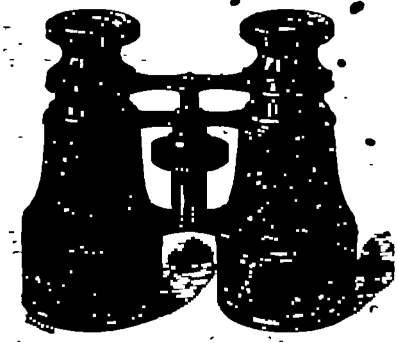
A DESCRIPTIVE LIST
OF
ANTHROPOMETRIC APPARATUS,
CONSISTING OF
INSTRUMENTS FOR MEASURING AND TESTING THE CHIEF PHYSICAL CHARACTERISTICS OF THE HUMAN BODY.

Standard tints, in glass, for colour of eyes Head measurement, its maximum length, breadth, and height. Height standing; height above chair when sitting. Span of arms. Breathing capacity. Weight. Strength of hand in squeezing; of arm as in drawing a bow. Appreciation of slight differences between weights. Eyesight: its keenness; appreciation of colours, judgment as regards squareness and angular divisions; judgment as regards divisions of a line into fractional parts. Hearing: its keenness, by distance of hearing a standard test-sound; appreciation of pitch; highest audible note. Reaction time to sound and sight.

Designed, under the direction of Mr. FRANCIS GALTON, Manufactured, and Sold by

THE CAMBRIDGE
SCIENTIFIC INSTRUMENT COMPANY,
ST. TIBB'S ROW, CAMBRIDGE, ENGLAND.

BROWNING'S BINOCULARS.



THE "ECONOMICAL", FIELD-GLASS.

This Binocular has achromatic object-glasses 1¼ inch in diameter, and sliding shades to shelter the object-glasses from sun or rain, and is fitted in a solid leather sling case, price £1 5s.; sent free

Illustrated Catalogue of Binoculars post free.

JOHN BROWNING, 63 STRAND, LONDON, W.C.

(UNLIKE MNEMONICS),

And Cure of Mind Wandering.

Any Book Learned in One Reading. Great Inducements to Correspondence Classes.

New Prospectus from Prof. LOISETTE, 37 New Oxford Street, London.

MINERALOGY AND GEOLOGY.

CHOICE SPECIMENS FOR MUSEUMS AND PRIVATE COLLECTORS: BERYLS, TOPAZES, RUTILES ON MATRIX, CELESTINE, OPALS, &c., &c.

RARE MINERALS FOR SCIENTIFIC RESEARCH; COLLECTIONS FOR STUDENTS AND PROSPECTORS.

VERY FINE POLISHED SECTIONS OF AMMONITES AND NAUTILI.

NEW SERIES OF ROCKS. MICROSCOPIC SLIDES.

Hammers, Chisels, and Blow-pipe Apparatus.

PRIVATE LESSONS AND EVENING CLASSES.

CATALOGUES ON APPLICATION.

SAMUEL HENSON,

277 STRAND, LONDON,

Opposite Norfolk Street.

NATURALISTS' GLASS-CAPPED BOXES.

Museums and Private Collectors supplied with Round and Rectangular Glass-capped Boxes from One Shilling per dozen. About 70 different sizes always in Stock. A cheap Glazed Box, 12 inches by 10 inches, for One Shilling. Samples Post Free, Two Shillings.

THOMAS D. RUSSELL,

PRIZE MEDALLIST, HEALTH EXHIBITION.

78 NEWGATE STREET, LONDON, E.C.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to

THOMAS BOLTON, 57 NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers Larval form of the Acorn Barnacle, Balanus balanoides, in the Nauplius stage, with drawing and description. He also sent out Salmon Fry, Grayling Ova, Lophopus crystallinus, Plumatella Ehrenbergi, Argulus foliaceus, Entomostraca, Melicerta ringens, various swimming Rotifers, Spongilla fluviatilis, Volvox globator, Desmids; also Hydra, Amœba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s., or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1s per bottle, with full instructions for use, from most Opticians. Post free for 1s. 3d from

EDWARD WARD, 249 Oxford Street, Manchester. [303

SIX PRIZE MEDALS

AWARDED FOR GEOLOGICAL COLLECTIONS.

Geological Collection especially adapted for Teaching as supplied to Science and Art Department, and used by all Lecturers and Teachers in Great Britain, &c.

New and Rare Minerals constantly arriving from all parts for selection of Single Specimens.

ROCK SECTIONS AND ROCK SPECIMENS:

The Largest Variety in England.

New Catalogues and Lists on application to—

JAMES R. GREGORY,

88 CHARLOTTE STREET, FITZROY SQUARE, LONDON.

Established 27 Years in London.

ROCKS, MINERALS, FOSSILS.

F. H. BUTLER,

Assoc. R. S. Mines Lond., M.A. Oxon., L.S.A. Lond., &c.,

Successor to the late R. TALLING,

180 BROMPTON ROAD, LONDON, S.W.

The most recent additions to stock include good specimens of the Palæozoic Crustacea *Palæocrangon socialis*, *P. Eskdalensis*, *Anthrapalæmon Parki*, *A. Etheridgei* and var. *latus*, *Ceratiocaris elongatus*, *C. scorpioides*, *Caryocaris Wrightii*, *Hymenocaris vermicauda*, *Acanthocaris elongatus*, and *Dithyrocaris glabra*, also many new rock-sections.

TO SCIENCE CLASSES AND SCHOOLS.

MOORE BROTHERS have been placed upon the list of Traders from whom Specimens may be purchased, with the assistance of the Science and Art Department, and Specimens of their Work may be seen at South Kensington.

PRICE LISTS ON APPLICATION.

MOORE BROTHERS,

OSTEOLOGISTS, DISARTICULATORS, ETC.,

15 KREMLIN DRIVE, TUE BROOK, LIVERPOOL.

Awarded Seven Medals and Three Diplomas.

TURTLE TABLETS.

A scientific discovery, by which WEST INDIA TURTLE, with all their lusciousness of calipee and calipash, are concentrated into Tablets. A Real Luxury for Epicures, Invalids, and Travellers. Each Tablet is sufficient to make Two Large Plates of Rich, Succulent, and Genuine Turtle Soup. Patronised by Royalty, and recommended by the highest Medical Authorities. In Nickel Boxes (with directions), price 2s. each, post free. Three Tablets for 5s. 6d. Six for 10s. 6d., post free.

CH. HOOPER & CO.,

164 Queen Victoria Street, London, E.C.

Two Doors from the "Times" Office.

Sale by Auction.

NATURAL HISTORY SPECIMENS.

MR. J. C. STEVENS will Sell by Auction at his Great Rooms, 38 King Street, Covent Garden, on MONDAY, March 14, at half-past 12 precisely, a small Collection of Minerals, the Property of a Gentleman; Shells, Eggs, Heads and Horns of Animals, Bird and Animal Skins, Feathers of the Moa from New Zealand, Insects and other Natural History Specimens, Books and Book-Cases, &c., &c.

On view the Saturday prior from 10 to 4, and Morning of Sale, and Catalogues had.

MACMILLAN'S MAGAZINE,

No. 329, for MARCH, Price 1*s.*, CONTAINS—

REPORT ON THE EAST ANGLIAN EARTHQUAKE OF APRIL 22, 1884. By RAPHAEL MELDOLA, F.C.S., F.I.C., F.R.A.S., &c., Professor of Chemistry in the Finsbury Technical College, City and Guilds of London Institute; and WILLIAM WHITE, F.E.S., Member of the Geologists' Association. Drawn up by R. MELDOLA, and read in Abstract at the Meeting of the Essex Field Club, February 28, 1885. With Maps and other Illustrations. Cheaper Issue, 8vo, 3s. 6d.

The *Athenæum* says:—"A distinctly valuable contribution to our knowledge of a subject of much obscurity, . . . The subject is one which only a few specialists will pursue within its narrower limits, but the curious facts collected, and the odd scraps of history referring to past earthquakes which have been gathered together are so numerous, so unexpected, and so well set, that the book will be found extremely interesting to the general reader, as well as a suggestive and severe study for the man of science."

MACMILLAN & CO., LONDON.

STANDARD SCIENTIFIC WORKS.

Twelfth Edition, Revised and Enlarged, with 5 Coloured Plates and 923 Woodcuts. Crown 8vo, 15*s.*

GANOT'S TREATISE ON PHYSICS.

A NEW BOOK BY MR. J. NORMAN LOCKYER.

THE CHEMISTRY OF THE SUN.

BY J. NORMAN LOCKYER, F.R.S.,

Correspondant of the Institute of France, Foreign Member of the Academy of the Lyncei of Rome, &c., &c., &c.

With Illustrations, Demy 8vo, 14s.

The *Times* says:—

"The phrase (the chemistry of the sun) would have had no meaning half a century ago, and the results achieved, as described in Mr. Lockyer's clear, emphatic, and unconventional style, must far exceed the most sanguine dreams of early spectroscopists. They certainly scatter many of the fine fancies which the poets have woven round the face of our 'spotless' luminary; but have given us in their place facts which no poet could ever have approached in his wildest imaginings. . . . . Mr. Lockyer begins at the beginning, and traces carefully and with clear deliberation the progress of solar spectroscopy from the time of Kepler to the present day. . . . . We have only been able in the most summary manner to refer to some of the points of interest in this new volume, the numerous illustrations in which deserve a word of praise."

The *Academy* says:—

"The splendid work embodied in this treatise demands ample recognition at the hands of a reviewer. . . . Mr. Norman Lockyer has conferred a great boon upon chemists, physicists, and astronomers by gathering into one connected whole the chief results of the researches which have been made on the chemistry of the sun. He freely acknowledges the labours of other workers, although his own share in these difficult inquiries has been indeed ample. The illustrative woodcuts of apparatus, spectra, and solar phenomena, as well as the numerous tables of measurements, form an important feature of the volume. Whatever judgment may be formed as to the validity of his hypothesis, the indefatigable ardour with which he has attacked the great problem of the constitution of the sun, and the skill with which he has devised fresh methods of testing and re-testing the meaning of the phenomena observed and the soundness of the arguments based thereon, merit the warmest acknowledgment."

The *Scotsman* says:—

"No man in this country can surpass Mr. Lockyer in the rare combination of painstaking accuracy in experimental work, sterling impartiality of judgment, and brilliant clearness in the expression of his opinions. His numerous published works have assigned him the highest place as an authority on solar physics. . . . . The author's work is to be highly commended; whatever conclusions scientific critics may arrive at as to the value of the hypothesis so ably advocated, there can be no two opinions about the uniform modesty and courteous respect for others which breathe through every page of the volume; the brilliant but clear style of the language in which his thoughts are clothed; the exemplary enthusiasm by which he carries his readers on over much which otherwise would be hard and dry; and the genuine scientific scholarship which never courts the tactics of the mountebank."

MACMILLAN & CO., LONDON.

WATSON & SONS' NEW HISTOLOGICAL MICROSCOPE.

AWARDED GOLD MEDAL, LIVERPOOL EXHIBITION, 1886.

FREE ON APPLICATION.

ILLUSTRATED CATALOGUE
OF
MICROSCOPES
AND
APPARATUS.

Classified List of 40,000 First-class Microscopic Objects.

A thoroughly first-rate Microscope at an extremely moderate price. It is mounted on an exceedingly firm brass foot, has sliding body for coarse adjustment, draw-tube, plane and concave mirrors, tube fitting of universal size for under-stage apparatus, with special arrangement for oblique illumination, set of diaphragms, with pin-hole stop, and is fitted with WATSON & SON'S improved form of fine adjustment, as supplied to their best instruments, which is perfectly free from all lateral motion, even when working with the high powers, and permits of the greatest possible delicacy of adjustment. The entire instrument is finished in the very best manner, and is unequalled in value at the price.

Microscope as illustrated, with "C" eye-piece, ⅛ and 1 inch first-class English objectives, giving a range of amplification from 75 to 700 diameters, in mahogany cabinet, price

£4 15s. 0d.

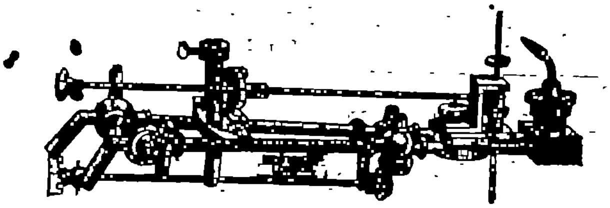
GOLD MEDAL,
International Inventions Exhibition, 1885.

NEW PATTERN OXY-HYDROGEN JET
FOR LIME-LIGHT LANTERN.



This jet, designed by Lewis Wright, Esq., gives a *most powerful light*, with a minimum of trouble. The lime-pin, of Bessemer steel, has a deep spiral cut in it, to which Newton's new check-action is fitted. By this arrangement, the whole lime-surface is used, yet the light never impinges twice on the same spot.

A new "cut-off," devised by Andrew Pringle, Esq., is also fitted to these jets, by which the light can be turned up or down without altering the taps.

Can be seen at work at 3 Fleet Street.

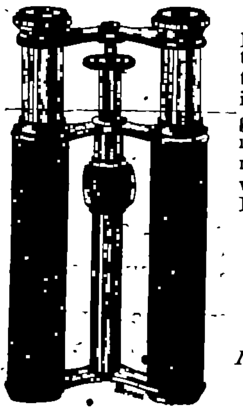
Price, best workmanship, 47s. 6d., as supplied to A. Pringle, Esq., who writes:—

"I write to let you know of the great success of the jet you made for me; it gives a grand light, and does not crack the limes as most jets do. Regarding the cut-off, every time I use it I like it better."

Price, without "cut-off" (as supplied to L. Wright, Esq.), 32s. 6d.

NEWTON & CO., 3 Fleet Street, London, E.C.

BINOCULAR TELESCOPES.



These Instruments are the most powerful Binoculars that can be made to be sufficiently portable for the tourist's use; their magnifying power is very great. They should be regarded as Telescopes; and where there is a sufficient amount of light, objects may be easily made out by them which would be invisible with any ordinary Binocular.

BINOCULAR TELESCOPE, with turning motion in centre to adjust it to the width of the eyes, in Solid Sling Leather Case £5

Illustrated Catalogue of Binoculars post free.

Candidates who do not belong to any regularly constituted Science or Art Class should apply before March 25 to the Special Local Secretary of the district, or, in case they do not reside within a Special Local Secretary's district, to the Secretary of the nearest Class which is to be examined in the subject they require. A fee for each candidate, not exceeding 2*s.* 6*d.* per day or evening, may be charged by the Local Committee, or the Special Local Secretary. The Special Local Secretaries for the London districts are as follows:—Chelsea and Westminster, J. R. Langler, Esq., 130 Horseferry Road, Westminster, S.W.; City (East) and Hackney, F. E. Harding, Esq., Murton House, Higham Road, Woodford, Essex; City (West) and Finsbury, W. H. Congreve, Esq., Birkbeck Institute, Bream's Buildings, E.C.; Greenwich and Deptford, J. J. Pakes, Esq., 10 Malpas Road, Brockley, S.E.; Lambeth (East), F. Dugard, Esq., 3 Sibella Road, Clapham, S.W.; Lambeth (West), F. Dugard, Esq., 3 Sibella Road, Clapham, S.W.; Marylebone, F. Pope, Esq., 18 Baker Street, Portman Square, W.; Southwark and Lambeth (North), A. Bourne, Esq., British and Foreign School Society, Boro' Road, S.E.; Tower Hamlets, E. J. Sharpe, Jun., Esq., 28 Oriental Street, Poplar, E.; Woolwich and Plumstead, R. T. Smith, Esq., 246 Burrage Road, Plumstead; Tottenham, J. F. Adams, Esq., 1, Talbot Road, Tottenham.

Individual candidates who do not reside near any place where a Local Examination Committee has been formed, may be examined in all Science and Art Subjects at the South Kensington Museum, as far as room will allow. A Registration Fee of 2*s.* 6*d.* per evening or day will be charged if application (on Form No. 325) is made before March 25, and of 5*s.* per evening afterwards, if before April 20, or a Composition Fee of 10*s.* for any number of evenings or days. Applications for examination at South Kensington cannot be received after April 20.

F.R.S.E., Late Member of the Institution of Civil Engineers.

New Edition (Third)

BY D. A. STEVENSON, B.Sc., F.R.S.E., and C. A. STEVENSON, B.Sc., Civil Engineer. Profusely Illustrated.

Edinburgh: A. & C. BLACK. London: LONGMANS.

Just Published, Price 7s. 6d.

PRACTICAL ELECTRICITY.

A Laboratory and Lecture Course, for First-Year Students of Electrical Engineering, based on the Practical Definitions of the Electrical Units.

BY W. E. AYRTON, F.R.S.,

Assoc. Mem. Inst. C.E., Professor of Applied Physics at the City and Guilds of London Central Institution. With Numerous Illustrations.

CASSELL & COMPANY, LIMITED, Ludgate Hill, London.

New Edition, Revised and Enlarged, 2 Vols. Demy 8vo, pp. lxxxiv and 5[illegible] —xxxvi. and 734, Cloth, 21s.

PHANTASMS OF THE LIVING.

By EDMUND GURNEY, M.A.,
FREDERIC W. H. MYERS, M.A., and
FRANK PODMORE, M.A.

Published with the Sanction of the Council of the Society for Psychical Research.

Times: "The main purpose of these remarkable volumes is to break new ground in the region of psychical inquiry."

Spectator: "We cannot too heartily praise the sobriety of judgment with which the conclusions have been drawn. The book will long be regarded as the most serious attempt hitherto made to record the least explicable of psychical impressions, and to estimate their value."

Mind: "The massive result of an inquiry conducted with astonishing vigour and pertinacity."

St. James's Gazette: "Mr. Gurney tests the stories in a thoroughly sceptical spirit . . . The chain of reasoning is a strong one, and the amount and goodness of the evidence are startling. . . . The book is cleverly and brightly written."

Pall Mall Gazette: "Useful and arduous work diligently and ably done."

Daily Telegraph: "The treatise is full of interest and suggestion."

Science (Boston): "Untiring zeal in collecting facts, and patience in seeking to make them accurate; learning of the solidest sort in discussing them; in theorising, subtlety and originality, and, above all, fairness—for the work absolutely reeks with candour."

London: TRÜBNER & CO., Ludgate Hill.

Crown 8vo, Price 4s. 6d.

HOURS WITH A THREE-INCH TELESCOPE.

By CAPTAIN W. NOBLE, F.R.A.S., &c.

With a Map of the Moon and 103 Woodcuts.

"May be recommended as a good work with which to begin the study of the celestial bodies. It is based wholly upon observation, and the illustrative cuts, notably the maps of the moon, are excellent."—*Scotsman.*

London: LONGMANS, GREEN, & CO.

W. F. STANLEY

Mathematical Instrument Manufacturer to H.M. Government Council of India, Science and Art Department, Admiralty, &c.

Mathematical, Drawing, and Surveying Instruments of Every Description.

Of the Highest Quality and Finish, at the most Moderate Prices

Illustrated Price List Post Free.

W. F. S. obtained the only Medal in the Great Exhibition of 1862 for Excellence of Construction of Mathematical Instruments, and the only GOLD MEDAL in the International Inventions Exhibition 1885 for Mathematical Work. Silver Medal, Architects' Exhibition, 1886.

Diary of Societies.

LONDON.

THURSDAY, MARCH 17.

oyal Society, at 4.30.—A Coal-Dust Explosion : W. Galloway.—Second Note on the Geometrical Construction of the Cell of the Honey-Bee : Prof. H. Hennessy, F.R.S.—The Embryology of Monotremata and Marsupialia : W. H. Caldwell.—On the Total Solar Eclipse of August 29, 1886 (Preliminary Account) : Prof. Schuster, F.R.S.

innean Society, at 8.—On Crustacea from Singapore : Alfred O. Walker.—The Genus Ficus, with Special Reference to Indo-Malayan and Chinese Species : Dr. George King.

hemical Society, at 8.—Ballot for the Election of Fellows.—The Action of Heat on Nitrogen Peroxide : Dr. A Richardson —The Formation of Naphthalenesulphonic Acid by means of Sulphuric Anhydride : Dr. Armstrong and W. P. Wynne.—On Supersaturated Saline Solutions : W. W. J. Nicol.

FRIDAY, MARCH 18.

nstitution of Civil Engineers, at 7.30.—The Manufacture of Raw Sugar ; Walter C. Kerr.—The Process and Machinery of Sugar-refining : Louis Martineau.

oyal Institution, at 9.—Mental Differences between Men and Women : George John Romanes, F R S.

SATURDAY, MARCH 19.

oyal Institution, at 3 —Sound : Lord Rayleigh, F.R.S.

SUNDAY, MARCH 20.

unday Lecture Society, at 4.—Our Unbidden Guests ; Parasites and their Histories : Dr. Andrew Wilson. (Illustrated by Diagrams)

MONDAY, MARCH 21.

ociety of Arts, at 8.—Machinery for Testing Materials, especially Iron and Steel : Prof. W. C Unwin, F.R.S.

ictoria Institute, at 8.—Krishna and Solar Myths : Rev. R. Collins.

TUESDAY, MARCH 22.

nthropological Institute, at 8.30.—On the Migrations of the Eskimo : Dr. H Rink.—Notes on the Inhabitants of the Polynesian Islands : Coutts Trotter.—Extracts from Notes on Natives of the Solomon Islands : communicated by Lieut. F Elton, R N

nstitution of Civil Engineers, at 8.—The Treatment of Gun-Steel : Colonel E. Maitland, R A. (Discussion.)

oyal Institution, at 3.—The Function of Respiration : Prof. Arthur Gamgee, F.R.S.

WEDNESDAY, MARCH 23.

eological Society, at 8.—Notes on the Structures and Relations of some of the Older Rocks of Brittany : Prof. T. G. Bonney, F.R S.—The Rocks of Sark, Herm, and Jethou : Rev. E. Hill.—Quartzite Boulders and Grooves in the Roger Mine at Dukinfield : James Radcliffe.

ociety of Arts, at 8.—The Living Organisms of the Air ; the Effect of Place and Climate on their Prevalence : Dr. Percy Frankland.

THURSDAY, MARCH 24.

oyal Society, at 4.30.—The following Papers will probably be read :—Preliminary Note on the "Radio-Micrometer," a New Instrument for Measuring the most Feeble Radiation : C. V. Boys.—Note to a Memoir on the Theory of Mathematical Form : A. B. Kempe, F.R S.—On Ellipsoidal Current-sheets : Prof. H. Lamb, F.R.S.—On the Magnetisation of Iron in Strong Fields : Prof. J. A. Ewing and W. Low.

nstitution of Civil Engineers, at 8.—On the Resistance of Faults in Submarine Cables : A. E. Kennelly

oyal Institution, at 3 —The Science of Thought : Prof. F. Max Müller.

FRIDAY, MARCH 25.

ociety of Arts, at 8.—Indian Coffee ; Frederick Clifford.

oyal Institution, at 9.—Colours of Thin Plates : Lord Rayleigh, F.R.S.

SATURDAY, MARCH 26.

hysical Society, at 3 —On the Production of the Finest Glass Fibres : C. V. Boys.—On Delicate Calorimetrical Thermometers ; and On the Expansion of Thermometer Bulbs under Pressure : Prof. Pickering

oyal Institution, at 3.—Sound : Lord Rayleigh, F.R S.

INVENTIONS EXHIBITION—GOLD MEDAL AWARDED.

DENT'S WATCHES.

TRADE MARK DENT

NEW ILLUSTRATED CATALOGUE of HIGH-CLASS WATCHES and CLOCKS at REDUCED PRICES, sent post free on application to E. DENT and Co., Makers to the Queen, 61 STRAND, LONDON, W.C., or 4 ROYAL EXCHANGE.

SECOND EDITION,

GRIFFIN'S

CHEMICAL HANDICRAFT.

PRICE 4*s.* 7*d.* POST FREE.

A CATALOGUE OF CHEMICAL APPARATUS;

ILLUSTRATED, CLASSIFIED, DESCRIPTIVE.

Demy 8vo, 480 pp., Illustrated with 1600 Woodcuts.

Most Complete and Cheapest List of Apparatus.

JOHN J. GRIFFIN AND SONS, 22 GARRICK STREET, LONDON, W.C.

TO SCIENCE CLASSES AND SCHOOLS.

MOORE BROTHERS have been placed upon the list of Traders from whom Specimens may be purchased, with the assistance of the Science and Art Department, and Specimens of their Work may be seen at South Kensington.

PRICE LISTS ON APPLICATION

MOORE BROTHERS,

OSTEOLOGISTS, DISARTICULATORS, ETC.,

15 KREMLIN DRIVE, TUE BROOK, LIVERPOOL.

Awarded Seven Medals and Three Diplomas.

TURTLE TABLETS.

A scientific discovery, by which WEST INDIA TURTLE, with all their lusciousness of callipee and callipash, are concentrated into Tablets A Real Luxury for Epicures, Invalids, and Travellers. Each Tablet is sufficient to make Two Large Plates of Rich, Succulent, and Genuine Turtle Soup. Patronised by Royalty, and recommended by the highest Medical Authorities. In Nickel Boxes (with directions), price 2*s.* each, post free. Three Tablets for 5*s.* 6*d.* Six for 10*s.* 6*d.*, post free.

Assoc. R. S. Mines Lond., M.A. Oxon., L.S.A. Lond., &c.,

Successor to the late R. TALLING,

180 BROMPTON ROAD, LONDON, S.W.

The most recent additions to stock include good specimens of the Palæozoic Crustacea *Palæocrangon socialis*, *P. Eskdalensis*, *Anthrapalæmon Parki*, *A. Etheridgei* and var. *latus*, *Ceratiocaris elongatus*, *C. scorpioides*, *Caryocaris Wrightii*, *Hymenocaris vermicauda*, *Acanthocaris elongatus*, and *Dithyrocaris glabra*, also many new rock-sections

BEST BLACK INK KNOWN.

DRAPER'S INK (DICHROIC).

DIFFERING FROM ANYTHING ELSE EVER PRODUCED.

Writing becomes a pleasure when this Ink is used. It has been adopted by the principal Banks, Public Offices, and Railway Companies throughout Ireland.

It writes almost instantly full Black.
Does not corrode Steel Pens.
Is cleanly to use, and not liable to Blot.

Flows easily from the Pen.
Blotting-paper may be applied at the moment of writing.

Can be obtained in London, through Messrs. BARCLAY & SONS, Farringdon Street; W. EDWARDS, Old Change; F. NEWBERY & SONS, Newgate Street ; and to be had of all Stationers.

BEWLEY & DRAPER (Limited), Dublin.

Second Edition, Re-written and greatly Enlarged. With 37 Illustrations on Wood. 8vo, price 24s.

SELECT METHODS IN CHEMICAL ANALYSIS

(CHIEFLY INORGANIC).

By WILLIAM CROOKES, F.R.S., V.P.C.S.,

Editor of the *Chemical News.*

London: LONGMANS, GREEN, & CO.

BERKHAMPSTED SCHOOL, HERTS.

Twenty-eight miles from Euston. Good Scholarships and Exhibitions. Laboratory, heated swimming-bath, workshop, &c. £52 per annum.—Address, Head-Master.

Excellent Copies of the **actual, natural Handwriting,** also of **Drawings, Music,** even of **elaborate Sketches, Programmes, Plans** (up to Double-Elephant size), **Shorthand,** and **Type-Writing** are easily, quickly, and cheaply produced by the

AUTOCOPYIST

Very fluid ink, used with ordinary pen and paper. Auto-Circulars resemble *written* letters. Used at the House of Lords, &c.

JAMES HOW & CO., 73 FARRINGDON STREET, LONDON.

HOLLOWAYS OINTMENT

AN INFALLIBLE REMEDY

For BAD LEGS, BAD BREASTS, OLD WOUNDS, SORES and ULCERS. If effectually rubbed on the Neck and Chest, it cures SORE THROATS, BRONCHITIS, COUGHS and COLDS; and for GOUT, RHEUMATISM, and all Skin Diseases it is unequalled.

DER NATURFORSCHER,

Wochenblatt zur Verbreitung der Fortschritte in den Naturwissenschaften, XIX Jahrgang.

Gegrundet von Dr. W. SKLAREK, u. herausgegeben von Dr. O. SCHUMANN, Privatdocent an der Universitat Tübingen.

Price for 52 Numbers, 16s. per annum, or 18s. 6d. post free

Tübingen: LAUPP.
London and Edinburgh: WILLIAMS & NORGATE.

THE "HANSA,"

Published since 1864 in Hamburg, is the only independent professional paper in Germany dedicated exclusively to Maritime Objects. Essays, Critiques, Reviews, Reports, Advertisements. Strict eye kept upon the development of Maritime Affairs in every respect. Every second Sunday one Number in 4to at least; frequent supplements and Drawings. Subscription at any time; preceding numbers of the year furnished subsequently. Price 12s. for twelve months. Advertisements 4d. a line widely spread by this paper; considerable abatement for 3, 6, 12 months' insertion. Business Office: Aug. Meyer and Dieckmann, Hamburg, Alterwall, 21. Edited by W. von FREEDEN M.R., Hamburg, Alexander Street 8.

On the 1st of every Month.

JOURNAL OF BOTANY,

BRITISH AND FOREIGN.

Edited by JAMES BRITTEN, F L S, British Museum.

CONTENTS:—Original Articles by leading Botanists.—Extracts, a Notices of Books and Memoirs.—Articles in Journals.—Botanical News. Proceedings of Societies

Price 1s 3d Subscription for One Year, payable in advance, 12s.

London: WEST, NEWMAN & CO., 54 Hatton Garden, E.C.

THE ZOOLOGIST:

A MONTHLY MAGAZINE OF NATURAL HISTORY.

Third Series. Edited by J. E. HARTING, F.L.S., F.Z.S., Member of th British Ornithologists' Union; contains—

Original Articles by well-known naturalists in every branch of zoolog habits of animals; arrival and departure of migratory birds; occurrence rare birds; distribution and migration of British fresh-water fish; new rare marine fish, local aquaria; British reptiles; British land and fres water mollusca, with remarks on the haunts and habits of the species; ar other matters of general interest to those who delight in natural histor Reports of the Linnean, Zoological, and Entomological Societies Revie of natural history books. Occasional translations from foreign zoologic Journals of important and interesting articles in various branches of zoolog There are occasional woodcuts.

JOHN VAN VOORST, 1 Paternoster Row.

NORTH BRITISH AGRICULTURIST

the chief Agricultural Journal in Scotland, circulates extensively amo Landowners, Farmers, Resident Agents, and others interested in th management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in tim for the Evening Mails, and contains Reports of all the principal British an Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIS as one of the best existing papers for Advertising Farms to be Let and Estat for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 14s.

Offices—377 High Street, Edinburgh; and 145 Queen Victoria Stree London, E.C. Money Orders payable to C. and R. ANDERSON.

On the 1st of every Month, price Sixpence.

THE ENTOMOLOGIST:

AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOG

Edited by JOHN T. CARRINGTON,

With the Assistance of

FREDERICK BOND, F.Z.S.
EDWARD A. FITCH, F.L.S.
RICHARD SOUTH.
J. JENNER WEIR, F.L.S
F. BUCHANAN WHITE, M.D.

Contains Articles by well-known Entomologists on all Branches of th Science; on Insects injurious or beneficial to Farm or Garden; Notes c Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthl Lists of Duplicates and Desiderata.

WOODCUT ILLUSTRATIONS and occasional LITHOGRAPHED and CHROM LITHOGRAPHED PLATES.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

NATURAL PHILOSOPHY.

A Text-Book of the Principles of Physics. By ALFRED DANIELL, M.A., LL.B., D.Sc., F.R.S.E., late Lecturer on Physics in the School of Medicine, Edinburgh. With Illustrations. Second Edition. Revised and Enlarged. Medium 8vo. 21s.

Elementary Practical Physics, Lessons in. By Professor BALFOUR STEWART, F.R.S., and W. W. HALDANE GEE, B.Sc. Crown 8vo.
Part I.—GENERAL PHYSICAL PROCESSES. 6s.
Part II.—ELECTRICITY AND MAGNETISM. [*Nearly ready.*
Part III.—OPTICS, HEAT, AND SOUND. [*In preparation.*

A School Course of Practical Physics. By the same Authors.
Part I.—ELECTRICITY AND MAGNETISM. [*In the press.*

Physics, Elementary Lessons in. By Professor BALFOUR STEWART, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d. (Questions on, 2s.)

Primer of Physics. By the same Author. With numerous Illustrations. New Edition, with Questions. 18mo. [illegible]s. [*Science Primers.*

On Light. Being the Burnett Lectures, delivered in Aberdeen in 1883-1885. By GEORGE GABRIEL STOKES, M.A., P.R.S., &c., Fellow of Pembroke College, and Lucasian Professor of Mathematics in the University of Cambridge. First Course. ON THE NATURE OF LIGHT.—Second Course. ON LIGHT AS A MEANS OF INVESTIGATION. Crown 8vo. 2s. 6d. each.
THIRD COURSE. ON THE BENEFICIAL EFFECTS OF LIGHT. [*In the press.*

Spectrum Analysis. Lectures delivered in 1868 before the Society of Apothecaries of London. By Sir HENRY E. ROSCOE, LL.D., F.R.S., Professor of Chemistry in the Owens College, Victoria University, Manchester. Fourth Edition, revised and considerably enlarged by the Author and by ARTHUR SCHUSTER, F.R.S., Ph.D., Professor of Applied Mathematics in the Owens College, Victoria University. With Appendices, numerous Illustrations, and Plates. Medium 8vo. 21s.

Mechanical Theory of Heat. By R. Clausius. Translated by WALTER R. BROWNE, M.A., late Fellow of Trinity College, Cambridge. Crown 8vo. 10s. 6d.

Heat. By P. G. Tait, M.A., Sec. R.S.E., formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh. Crown 8vo. 6s.

Light: A Course of Experimental Optics, CHIEFLY WITH THE LANTERN. By LEWIS WRIGHT. With 200 Engravings and Coloured Plates. Crown 8vo. 7s. 6d.

Natural Philosophy for Beginners. By I. TODHUNTER, M.A., F.R.S. Fcap. 8vo. Part I.—The Properties of Solid and Fluid Bodies. With Illustrations. 3s. 6d. Part II.—Sound, Light, and Heat. 3s. 6d.

Electrostatics and Magnetism, Reprints of Papers on. By Sir WILLIAM THOMSON, D.C.L., LL.D., F.R.S., F.R.S.E., Fellow of St. Peter's College, Cambridge, and Professor of Natural Philosophy in the University of Glasgow. Second Edition. Medium 8vo. 18s.

Electricity and Magnetism. By Professor SILVANUS THOMPSON. With numerous Illustrations. Fcap. 8vo. 4s. 6d.

Electricity and Magnetism, Absolute MeaSUREMENTS IN. By Professor ANDREW GRAY, M.A., F.R.S.E. Pott 8vo. 3s. 6d.

Electric Light Arithmetic. By R. E. Day, M.A. Pott 8vo. 2s.

Heat and Electricity, A Collection of ExAMPLES ON. By H. H. TURNER, B.A., Fellow of Trinity College, Cambridge. Crown 8vo. 2s. 6d.

Steam, An Elementary Treatise on. By J. PERRY, C.E., Professor of Engineering in the Imperial College of Engineering, Yedo. With Illustrations, Numerical Examples, and Exercises. Fcap. 8vo. 4s. 6d.

Sound, Elementary Lessons on. By Dr. W. H. STONE. With Illustrations. Fcap. 8vo. 3s. 6d.

Units and Physical Constants. By J. D. EVERETT, M.A., D.C.L., F.R.S., F.R.S.E., Professor of Natural Philosophy, Queen's College, Belfast. Second Edition. Globe 8vo. 5s.

Applied Mechanics: An Elementary General Introduction to the Theory of Structures and Machines. By JAMES H. COTTERILL, F.R.S., Associate Member of the Council of the Institution of Naval Architects, Associate Member of the Institution of Civil Engineers, Professor of Applied Mechanics in the Royal Naval College, Greenwich. Medium 8vo. 18s.

NATURAL PHILOSOPHY—*Continued.*

The Kinematics of Machinery. Outlines of a Theory of Machines. By Professor F. REULEAUX. Translated and Edited by Professor A. B. W. KENNEDY, C.E. With 450 Illustrations. Medium 8vo. 21s.

The Mechanics of Machinery. By A. B. W. KENNEDY, M.Inst.C.E., Professor of Engineering and Mechanical Technology in University College, London. With numerous Illustrations. Crown 8vo. 12s. 6d.

Elementary Science, Numerical Tables and CONSTANTS IN. By SYDNEY LUPTON, M.A., F.C.S., F.C.I. Globe 8vo. 2s. 6d.

Chemical Arithmetic. With 1200 Examples. By the same Author. Second Edition. Globe 8vo. 4s. 6d.

ASTRONOMY.

Popular Astronomy. By S. Newcomb, LL.D., Professor U.S. Naval Observatory. With 112 Illustrations and 5 Maps of the Stars. Second Edition, revised. 8vo. 18s.

Popular Astronomy. By Sir G. B. Airy, K.C.B., F.R.S., late Astronomer-Royal. With numerous Illustrations. Fcap. 8vo. 4s. 6d.

Astronomy, Elementary Lessons in. By J. NORMAN LOCKYER, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 5s. 6d. (Questions on, 1s. 6d.)

The Chemistry of the Sun. By J. Norman LOCKYER, F.R.S. With Illustrations. Demy 8vo. 14s.

Primer of Astronomy. By J. Norman LOCKYER, F.R.S. With numerous Illustrations. New Edition. 18mo. 1s. [*Science Primers.*

CHEMISTRY.

Inorganic and Organic Chemistry. A Complete Treatise on Inorganic and Organic Chemistry. By Sir HENRY E. ROSCOE, F.R.S., and Professor C. SCHORLEMMER, F.R.S. With numerous Illustrations. Medium 8vo.
Vols. I. and II.—INORGANIC CHEMISTRY.
Vol. I.—The Non-Metallic Elements. 21s. Vol. II. Part I.—Metals. 18s. Vol. II. Part II.—Metals. 18s.
Vol. III.—ORGANIC CHEMISTRY. Three Parts.
The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. With numerous Illustrations. Medium 8vo. Parts I. and II., 21s. each. Part III., 18s.

Elements of Chemical Physics. By Josiah P. COOKE, Junr., Erving Professor of Chemistry and Mineralogy in Harvard University. Fourth Edition. Royal 8vo. 21s.

A Manual of the Chemistry of the Carbon COMPOUNDS, OR ORGANIC CHEMISTRY. By C. SCHORLEMMER, F.R.S., Professor of Chemistry in the Victoria University, the Owens College, Manchester. With Illustrations. 8vo. 14s.

The Elements of Thermal Chemistry. By M. M. PATTISON MUIR, M.A., F.R.S.E., Fellow and Prælector of Chemistry in Gonville and Caius College, Cambridge; Assisted by DAVID MUIR WILSON. 8vo. 12s. 6d.

The Study of Chemistry, an Introduction TO. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

Compounds of Carbon; or, Organic Chemistry, an Introduction to the Study of. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

Chemistry, Elementary Lessons in. By Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d. Problems adapted to the same, by Professor THORPE. With Key. 18mo. 2s.

Owen's College Junior Course of Practical CHEMISTRY. By F. JONES. With Preface by Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 2s. 6d.

Questions on Chemistry. A Series of Problems and Exercises in Inorganic and Organic Chemistry. By F. JONES, F.R.S.E., F.C.S. Fcap. 8vo. 3s.

Primer of Chemistry. By Sir Henry E. ROSCOE, F.R.S. With numerous Illustrations. New Edition. With Questions. 18mo. 1s. [*Science Primers.*

ESSEX FIELD CLUB SPECIAL MEMOIRS, VOL. I.

REPORT ON THE EAST ANGLIAN EARTHQUAKE OF APRIL 22, 1884. By RAPHAEL MELDOLA, F.C.S., F.I.C., F.R.A.S., &c., Professor of Chemistry in the Finsbury Technical College, City and Guilds of London Institute; and WILLIAM WHITE, F.E.S., Member of the Geologists' Association. Drawn up by R. MELDOLA, and read in Abstract at the Meeting of the Essex Field Club, February 28, 1885. With Maps and other Illustrations. Cheaper Issue, 8vo, 3s. 6d.

The *Athenæum* says:—"A distinctly valuable contribution to our knowledge of a subject of much obscurity. . . . The subject is one which only a few specialists will pursue within its narrower limits, but the curious facts collected, and the odd scraps of history referring to past earthquakes which have been gathered together are so numerous, so unexpected, and so well set, that the book will be found extremely interesting to the general reader, as well as a suggestive and severe study for the man of science."

MACMILLAN & CO., LONDON.

Printed by RICHARD CLAY AND SONS, at 7 and 8 Bread Street Hill, Queen Victoria Street, in the City of London, and Published by MACMILLAN AND CO., at the Office, 29 and 30 Bedford Street, Covent Garden.—THURSDAY, March 17, 1887.

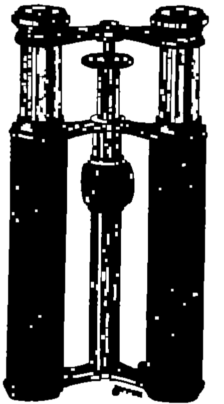
INSTRUMENTS FOR MEASURING AND TESTING THE CHIEF PHYSICAL CHARACTERISTICS OF THE HUMAN BODY.

Standard tints, & glass, for colour of eyes Head measurement, its maximum length, breadth, and height. Height standing, height above chair when sitting. Span of arms Breathing capacity. Weight Strength of hand in squeezing; of arm as in drawing a bow. Appreciation of slight differences between weights. Eyesight. its keenness; appreciation of colours, judgment as regards squareness and angular divisions; judgment as regards divisions of a line into fractional parts. Hearing: its keenness, by distance of hearing a standard test-sound; appreciation of pitch; highest audible note. Reaction time to sound and sight

Designed, under the direction of Mr. FRANCIS GALTON, Manufactured, and Sold by

THE CAMBRIDGE
SCIENTIFIC INSTRUMENT COMPANY,
ST. TIBB'S ROW, CAMBRIDGE, ENGLAND.

BINOCULAR TELESCOPES.



These Instruments are the most powerful Binoculars that can be made to be sufficiently portable for the tourist's use; their magnifying power is very great. They should be regarded as Telescopes; and where there is a sufficient amount of light, objects may be easily made out by them which would be invisible with any ordinary Binocular.

BINOCULAR TELESCOPE, with turning motion in centre to adjust it to the width of the eyes, in Solid Sling Leather Case £5

Illustrated Catalogue of Binoculars post free.

UNIVERSITY COLLEGE, LONDON.

ADVANCED INORGANIC CHEMISTRY.

DR. S. RIDEAL will give a Course of Thirty Lectures on Mondays, Wednesdays, and Fridays, at 4 p m , commencing APRIL 20. The Course is fitted for Students reading for Honours in Chemistry at the University of London July Examinations. Recent Progress in Physical Chemistry and the study of the Rarer Elements form part of the Course. Fee, £2 2s.

J. M. HORSBURGH M.A., Secretary.

UNIVERSITY COLLEGE, LONDON.

The PROFESSORSHIP of CHEMISTRY will be Vacant at the end of the present Session by the resignation of Prof A. W WILLIAMSON, F R S. Applications should be sent in not later than APRIL 30 to the SECRETARY of the College, from whom information may be obtained as to the Duties and Emoluments of the Professorship.

J M HORSBURGH, M.A., Secretary.

CURRICULUM OF THE M.D. DEGREE, LONDON.

Students who have Matriculated and are intending to enter or who have already entered at any one of the London Medical Schools for the purely Medical Portion of their Studies, can prepare for the PRELIMINARY SCIENTIFIC EXAMINATION at University College, under Prof. Williamson, LL D., F R.S., Prof Carey Foster, F.R.S., Prof. Oliver, F R S., and Prof Lankester, LL.D., F.R.S

Fee for the complete Course of Study required, including Lectures and Laboratory Work, 35 Guineas.

For particulars apply to the SECRETARY, University College, Gower Street.

DEMONSTRATORSHIP IN PHYSICS.

The PROFESSOR of PHYSICS in University College, Liverpool, is prepared to nominate a DEMONSTRATOR to take part charge of Laboratory Students and Junior Classes from next OCTOBER. The Salary offered is from £80 to £100 a year with some opportunity for Private Tuition and Special Classes in allied subjects, such as Geography.

Applications, stating experience and qualifications, to be sent in to Prof. OLIVER LODGE, who will furnish further particulars.

KING'S COLLEGE, LONDON.

BACTERIOLOGY.

A Practical Course will be given in the Physiological Laboratory for four days a week, from 2 to 4.30, by E. CROOKSHANK, M.B. The Class will meet on May 17, and last for three weeks.

For Syllabus and further information, apply to

J. W CUNNINGHAM, Secretary.

EAST GRINSTEAD COLLEGIATE SCHOOL

MAYPOLE ROAD, SUSSEX.

The object of the School is to afford a Sound Education, which will fit boys for either Professional or Commercial Life. Most careful attention is paid to the requirements of boys intended for commercial pursuits. Boys are received from seven to fourteen years of age. There is a Junior Class, specially adapted to prepare the younger boys for the work of the higher classes. Each pupil will receive careful attention, especially in those subjects wherein he is weak. No injurious cramming encouraged. The course of Instruction includes all the subjects required at the various public examinations. The Principal has had many years' experience in good schools, and has proved himself a most successful Master. The Fees are moderate.—For Prospectus and particulars, apply to the PRINCIPAL.

AGRICULTURAL COLLEGIATE SCHOOL.

EAST GRINSTEAD, SUSSEX.

For Sons of Gentlemen, from seven years of age. The Course of Studies or Instruction is designed to prepare boys to occupy the positions of Landowners, Land Agents, Farmers, Intending Colonists, &c. It provides full instruction in the practice and science of Agriculture and Estate Management, Management of Live Stock, Dairy Farming, Agricultural Chemistry, &c. Pupils are prepared for all the Examinations.

The College offers the following advantages:—A most superior education. A Staff of Masters selected for their qualifications as Scholars and their tried ability as Teachers. A Boarding Department carefully supervised and excellently appointed; its diet liberal, and all arrangements calculated to develop gentlemanly habits, and to produce feelings of self-respect.

The strictest attention to the moral and religious training of Pupils. Fees most moderate. References of high character to Parents of Pupils.

Prospectus and all particulars on application to the PRINCIPAL.

A FRENCH GENTLEMAN, with First-rate Scholastic Recommendations, has a French Class for Army Pupils at 2 Colville Gardens, Bayswater. He and his wife also receive as Boarders two or three Young Men who wish to study the language for business or conversational purposes.—Address M. ALFRED VIGIER, Swanley, Kent.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to

THOMAS BOLTON, 57 NEWHALL STREET, BIRMINGHAM

Who last week sent to his Subscribers Spirorbis nautiloides, with drawing and description. He also sent out Vaucheria (in fructification), Zygnema, Freshwater Mussel Spat, Lophopus crystallinus, Spongilla fluviatilis, Grantia compressa, Stephanoceros Eichhornii, Melicerta ringens, Argulus foliaceus, Volvox globator, Desmids; also Hydra, Amoeba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1s. per bottle, with full instructions for use, from most Opticians.

Post free for 1s. 3d from

EDWARD WARD, 249 Oxford Street, Manchester. [503

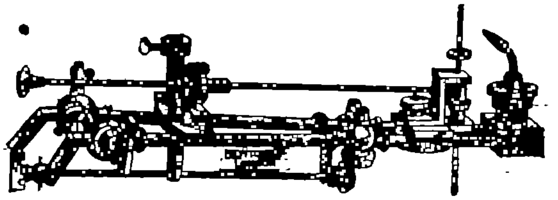
GOLD MEDAL,
International Inventions Exhibition, 1885.

NEW PATTERN OXY-HYDROGEN JET
FOR LIME-LIGHT LANTERN.



This jet, designed by Lewis Wright, Esq., gives a *most powerful light*, with a minimum of trouble. The lime-pin, of Bessemer steel, has a deep spiral cut in it, to which Newton's new check-action is fitted. By this arrangement, the whole lime-surface is used, yet the light never impinges twice on the same spot.

A new "cut-off," devised by Andrew Pringle, Esq., is also fitted to these jets, by which the light can be turned up or down without altering the taps.

Can be seen at work at 3 Fleet Street.

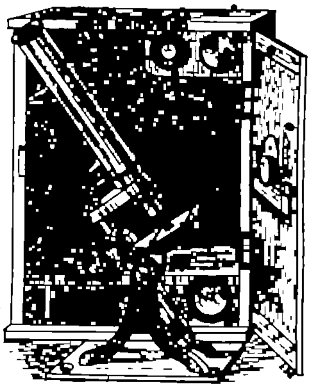
Price, best workmanship, 47s. 6d., as supplied to A. Pringle, Esq., who writes:—

"I write to let you know of the great success of the jet you made for me, it gives a grand light, and does not crack the limes as most jets do. Regarding the cut-off, every time I use it I like it better."

Price, without "cut-off" (as supplied to L. Wright, Esq.), 32s. 6d.

NEWTON & CO., [illegible] Fleet Street, London, E.C.

BROWNING'S
"PERFECT" MICROSCOPE.



The body is made entirely of brass and gun-metal, with rack-motion and fine screw adjustment. Three achromatic powers of excellent defining power, 1-inch, ½-inch, and ¼-inch; adjusting slide-holder to stage, revolving diaphragm, hand-forceps, stage-forceps, live-cage, &c. The whole packed in upright Mahogany Cabinet, with drawer for slides, dissecting-knives, &c.

Price £3 15s. 0d.

OWENS COLLEGE, MANCHESTER.

A GILCHRIST SCHOLARSHIP of the value of £50 per annum, tenable in the Owens College for three years, is offered for competition among Candidates at the Matriculation Examination of the University of London in June 1887.

Candidates for this Scholarship are required to send in their names to the Principal of the College, on or before June 1.

For full particulars, apply to

HENRY WM. HOLDER, M.A., Registrar.

UNIVERSITY COLLEGE, LONDON.

The PROFESSORSHIP of CHEMISTRY will be Vacant at the end of the present Session by the resignation of Prof. A. W. WILLIAMSON, F.R.S. Applications should be sent in not later than APRIL 30 to the SECRETARY of the College, from whom information may be obtained as to the Duties and Emoluments of the Professorship.

J. M. HORSBURGH, M.A., Secretary.

GUY'S HOSPITAL MEDICAL SCHOOL.

The SUMMER SESSION commences on MONDAY, May 2.

The Hospital contains, besides the beds for Medical and Surgical Cases, wards for Obstetric, Ophthalmic, and other special Departments.

Special Classes are held in the Hospital for Students preparing for the Examinations of the University of London and other Examining Boards.

APPOINTMENTS.—The House Surgeons and House Physicians, the Obstetric Residents, Clinical Assistants, and Dressers are selected from the Students according to merit and without payment. There are also a large number of Junior Appointments, every part of the Hospital Practice being systematically employed for instruction.

ENTRANCE SCHOLARSHIPS.—Open Scholarship of 125 guineas, in Classics, Mathematics, and Modern Languages. Open Scholarship of 125 guineas, in Chemistry, Physics, Botany, and Zoology.

Students entering in May are eligible for the Open Scholarships competed for in September.

Seventeen Scholarships, Prizes, and Medals varying from £50 to £10 each are open for competition to all the Students.

The Hospital is in close proximity to the Metropolitan, District, South-Eastern, Brighton, Chatham, North London, and Great Eastern Railway systems.

For Prospectus apply to the Dean, Dr. F. TAYLOR, Guy's Hospital, London, S.E.

March 1887.

GUY'S HOSPITAL MEDICAL SCHOOL.

OPEN SCHOLARSHIPS.

A Scholarship of the value of 125 Guineas will be offered for Open Competition on WEDNESDAY, September 28. Subjects of Examination:—Classics, Mathematics, and Modern Languages. A second Scholarship, also of the value of 125 Guineas, will be offered for Open Competition on the same day. Subjects of Examination:—Inorganic Chemistry, Physics, Botany, and Zoology.

For further particulars apply to the DEAN, Guy's Hospital, S.E.

LONDON HOSPITAL AND MEDICAL COLLEGE,

MILE-END, E.

The SUMMER SESSION will commence on MONDAY, May 2.

The New College Buildings are now complete, and afford more than double the former accommodation.

Intending Students are advised that, under the new regulations of the Examining Board in England, it is exceedingly advantageous to enter for the Summer Session. Students now entering are also eligible for the Entrance Scholarships in September.

The Hospital contains nearly 800 beds, and is the largest General Hospital in Great Britain.

General Fee for Lectures and Hospital Practice, 90 guineas in one sum, or 100 guineas in three instalments. The Resident and other Hospital Appointments are free to full Students.

Special entries may be made for Medical and Surgical Practice, also for the course of Practical Surgery.

The London Hospital is now in direct communication by rail and tram with all parts of the Metropolis, and the Metropolitan, Metropolitan District, South-Eastern, and East London Railways have stations within a minute's walk of the Hospital and College.

For Prospectus and particulars apply to

MUNRO SCOTT, Warden.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, S.E.

The SUMMER SESSION will commence on May 2. Students entering in the summer are eligible to compete for the Science Scholarships of 125 Guineas and £60, awarded in October.

There are numerous Prizes and Scholarships, and all Appointments are open to Students without extra charge.

Special Classes for the Examinations of the University of London are held throughout the year. A Register of Approved Lodgings and of Private Families receiving Students to reside is kept in the Secretary's Office.

Prospectus and all particulars can be obtained from the Medical Secretary, Mr. G. RENDLE.

W. M. ORD, Dean.

EAST GRINSTEAD COLLEGIATE SCHOOL,

MAYPOLE ROAD, SUSSEX.

The object of the School is to afford a Sound Education, which will fit boys for either Professional or Commercial life. Most careful attention is paid to the requirements of boys intended for commercial pursuits. Boys are received from seven to fourteen years of age. There is a Junior Class, specially adapted to prepare the younger boys for the work of the higher classes. Each pupil will receive careful attention, especially in those subjects wherein he is weak. No injurious cramming encouraged. The course of Instruction includes all the subjects required at the various public examinations. The Principal has had many years' experience in good schools, and has proved himself a most successful Master. The Fees are moderate.—For Prospectus and particulars, apply to the PRINCIPAL.

AGRICULTURAL COLLEGIATE SCHOOL,

EAST GRINSTEAD, SUSSEX.

For Sons of Gentlemen, from seven years of age. The Course of Studies or Instruction is designed to prepare boys to occupy the positions of Landowners, Land Agents, Farmers, intending Colonists, &c. It provides full instruction in the practice and science of Agriculture and Estate Management, Management of Live Stock, Dairy Farming, Agricultural Chemistry, &c. Pupils are prepared for all the Examinations.

The College offers the following advantages:—A most superior education. A Staff of Masters selected for their qualifications as Scholars and their tried ability as Teachers. A Boarding Department carefully supervised and excellently appointed, its diet liberal, and all arrangements calculated to develop gentlemanly habits, and to produce feelings of self-respect.

The strictest attention to the moral and religious training of Pupils. Fees most moderate. References of high character to Parents of Pupils.

Prospectus and all particulars on application to the PRINCIPAL.

A FRENCH GENTLEMAN, with First-rate Scholastic Recommendations, has a French Class for Army Pupils at 2 Colville Gardens, Bayswater. He and his wife also receive as Boarders two or three Young Men who wish to study the language for business or conversational purposes.—Address M. ALFRED VIGIER, Swanley, Kent.

HOW & CO.'S POCKET MICROSCOPE LAMP, 8s. 6d.

MICRO-PETROLOGY.—Sections of Pitchstones, Obsidians, Granites, Syenites, Diorites, Gabbros, Dolerites, Basalts, Tachylites, Trachytes, Andesites, Porphyrites, Rhyolites, Lavas, Ashes, Gneiss, Schists, Limestones, &c., price 1s. 6d. each.

JAMES HOW & CO., 73 FARRINGDON STREET, LONDON.

NORTH BRITISH AGRICULTURIST,

the chief Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching that Class.

Price 3d. By post 3½d. Annual Subscription, payable in advance, 14s.

Offices—377 High Street, Edinburgh, and 145 Queen Victoria Street, London, E.C. Money Orders payable to C. and R. ANDERSON.

Now ready, price 6s.

Vol XXI., New Series, Vol. I., Part III., APRIL 1887.

THE JOURNAL OF ANATOMY AND PHYSIOLOGY,

NORMAL AND PATHOLOGICAL.

CONDUCTED BY

Profs. HUMPHRY, TURNER, and McKENDRICK.

Contents.

1. Action of Infused Beverages on Peptic and Pancreatic Digestion. By J. W. Fraser, M.D.
2. Relations of Mammalia to Ichthyopsida and Sauropsida. By T. W. Shore, M.D.
3. Changes produced in Lungs of Sheep by a Parasitic Worm. By H. Bowley, M.B.
4. Menstruation—Its Nerve Origin—Not a Shedding of Mucous Membrane. By J. Oliver, M.B.
5. Pressure Changes in Skeleton. By W. Arbuthnot Lane, M.S.
6. Morphology of Sacral Plexus in Man. By A. M. Paterson, M.D.
7. Behaviour of Bacteria in the Digestive Tract. By A. Macfadyen, M.D.
8. Double Superior Vena Cava, Right Pulmonary Veins opening into Right Auricle. By D. Hepburn, M.B.
9. Method of Combining Weigert's Hæmatoxylene-Copper Stain with Use of Freezing Microtome. By D. J. Hamilton, M.B.
10. Intra-Peritoneal Blood Transfusion, and Fate of Absorbed Blood. By W. Hunter, M.D.
11. Variability in Human Structure in Different Races of Men. By Sir William Turner.
12. Remarks on Centenarians. By Prof. Humphry.
13. Vaccination, and Subsequent Amputation of Supernumerary Fingers. By R. Cory, M.D.
14. Cases of Single Kidney. By F. W. Menzies, M.B.
15. Variations in Nerves of Human Body. By D. Hepburn, M.B.
16. Nervous Supply of Musculus Sternalis. By J. C. Lamont, M.B.
17. Abbe's Apochromatic Micro-Objectives and Compensating Eye-Pieces. By Adolf Schulze.

WILLIAMS & NORGATE, 14 Henrietta Street, Covent Garden, London; and 20 South Frederick Street, Edinburgh.

On the 1st of every Month, price Sixpence.

THE ENTOMOLOGIST:

AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOGY.

Edited by JOHN T. CARRINGTON,

With the Assistance of

FREDERICK BOND, F.Z.S. | RICHARD SOUTH.
EDWARD A. FITCH, F.L.S. | J. JENNER WEIR, F.L.S.
F. BUCHANAN WHITE, M.D.

Contains Articles by well-known Entomologists on all Branches of the Science; on Insects injurious or beneficial to Farm or Garden; Notes on Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthly Lists of Duplicates and Desiderata.

WOODCUT ILLUSTRATIONS and occasional LITHOGRAPHED and CHROMO-LITHOGRAPHED PLATES.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

DER NATURFORSCHER,

Wochenblatt für Verbreitung der Fortschritte in den Naturwissenschaften, XIX. Jahrgang.

Gegründet von Dr. W. SKLAREK, u. herausgegeben von Dr. O. SCHUMANN, Privatdocent an der Universität Tübingen.

Price for 52 Numbers, 16s. per annum, or 18s. 6d. post free.

Tübingen: LAUPP.

London and Edinburgh: WILLIAMS & NORGATE.

THE "HANSA,"

Published since 1864 in Hamburg, is the only independent professional paper in Germany dedicated exclusively to Maritime Objects. Essays, Critiques, Reviews, Reports, Advertisements. Strict eye kept upon the development of Maritime Affairs in every respect. Every second Sunday one Number in 4to at least; frequent supplements and drawings. Subscription at any time; preceding numbers of the year furnished subsequently. Price 12s. for twelve months. Advertisements 4d. a line widely spread by this paper; considerable abatement for 3, 6, 12 months' insertion. Business Office: Aug. Meyer and Dieckmann, Hamburg, Alterwall, 28. Edited by W. von FREEDEN M.R., Hamburg, Alexander Street, 8.

FRY'S PURE

CONCENTRATED
SOLUBLE **COCOA**

Prepared by a new and special scientific process
Securing extreme solubility, and developing
the finest flavour of the Cocoa.

CHEAP WATER SUPPLY FOR MANSIONS, &c.
BAILEY'S PATENT
HOT-AIR PUMPING ENGINES.

No Danger! No Gas! No Steam! No Boiler! No Explosions! No Nuisance of any kind! Require little attention! No skilled labour! Will burn any kind of fuel! Costs less to work than any other kind of engine

Bailey's Hot-air Pump, Complete, ready for work, to supply any quantity of Water up to 4000 Gallons daily, £32. Pamphlets and Particulars free.

W. H. BAILEY & CO., Hydraulic Engineers, &c. Albion Works, Salford, Manchester.

Pumping Salt Water at Colwyn Bay Hotel.

Supplying a Mansion.

Diary of Societies.

LONDON.

THURSDAY, MARCH 31.

ROYAL SOCIETY, at 4.30.—Note on the Development of Voltaic Electricity by Atmospheric Oxidation : Dr. Alder Wright, F R S , and C Thompson.—On Clausius's Formula for the change of state from Liquid to Gas applied to Messrs. Ramsay and Young's Observations : Prof Fitzgerald, F.R S —The Influence of Stress and Strain on the Physical Properties of Matter ; Part III. Magnetic Induction H. Tomlinson.—Note on a New Constituent of Blood Serum : Dr. Wooldridge.—Note on the Fossil Remains of a Chelonian Reptile, Ceratochelys sthenurus, from Lord Howe's Island : Prof. Huxley, F.R.S —(1) Action of Caffein and Theine upon Voluntary Muscle ; (2) Contributions to our Knowledge of the Connexion between Chemical Constitution and Physiological Action—Preliminary Communication on the Action of certain Aromatic Bodies : Dr. Lauder Brunton, F R S., and Dr. Cash

ROYAL INSTITUTION, at 3.—The Science of Thought : Prof F. Max Muller.

FRIDAY, APRIL 1.

GEOLOGISTS' ASSOCIATION, at 8.—On the Metamorphosis of Basic Igneous Rocks : J J. Harris Teall.

INSTITUTION OF CIVIL ENGINEERS, at 7 30.—Hydraulic Appliances at the Forth Bridge Works : E. W Moir.

ROYAL INSTITUTION, at 9 —Light as an Analytic Agent : Prof. Dewar.

SATURDAY, APRIL 2

ROYAL INSTITUTION, at 3.—Sound . Lord Rayleigh, F.R.S.

MONDAY, APRIL 4.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Further Notes and Experiments on the Composition and Manurial Value of Filter-Pressed Sewage Sludge ; Dr. J M H. Munro.

ODONTOLOGICAL SOCIETY, at 8.—On the Pathology of Pyorrhœa Alveolaris · F Newland Pedley.

VICTORIA INSTITUTE, at 8.—The Pedigree of Coral Reefs : S R. Pattison.

ROYAL INSTITUTION, at 5.—General Monthly Meeting.

TUESDAY, APRIL 5.

ZOOLOGICAL SOCIETY, at 8 30 —On a Specimen of Ziphius recently obtained near Dunedin, New Zealand · Prof John H. Scott and Prof. T. Jeffery Parker —On some Points in the Morphology of the Wings of Birds : Richard S Wray Communicated by Prof Flower.—A Revision of the Sub-family Libellulinæ, with Descriptions of New Genera and Species W. F Kirby.—Contributions to the Anatomy of Earthworms, Nos. I., II., III F. E. Beddard

INSTITUTION OF CIVIL ENGINEERS, at 8.—Printing Machinery : E A. Clowes.

WEDNESDAY, APRIL 6.

ROYAL ASTRONOMICAL SOCIETY, at 8.

GEOLOGICAL SOCIETY, at 8.—On the Rocks of the Malvern Hills, Part II. : Frank Rutley.—A Preliminary Inquiry into the Genesis of the Crystalline Schists of the Malvern Hills : Dr. C Callaway.—On the Alleged Conversion of Crystalline Schists into Igneous Rocks in County Galway Dr. C. Callaway.

ENTOMOLOGICAL SOCIETY, at 7 —Notes in 1886 on Lepidopterous Larvæ and Pupæ : Edward B Poulton, M A.

PARKES MUSEUM OF HYGIENE, at 5.—Metropolitan Sewage Disposal : J. Bailey-Denton

THURSDAY, APRIL 7.

LINNEAN SOCIETY, at 8 —The Gentians—Notes and Queries : Prof. Huxley.—Gephyreans of Mergui Archipelago.—British Heterœcious Uredines C. B. Plowright

MATHEMATICAL SOCIETY, at 8.—On some Properties of Simplicissima, with especial regard to the Related Spherical Loci : W. J. C. Sharp.—On the Intersections of a Circle and a Plane Curve of any Degree : Prof. Genese —A New Theory of Harmonic Polygons · Rev. T. C. Simmons —On Briot and Bouquet's Theory of the Differential Equation $F\left(u, \frac{du}{dz}\right) = 0$ · Prof Cayley, F R S.—Two Points in the Plane of a Triangle and a Cubic through them : R. Tucker.

CHEMICAL SOCIETY, at 8 —Researches on the Constitution of Azo- and Diazo-Derivatives ; Diazo-amido-compounds, Part II. : R. Meldola, F R.S., and F. W. Streatfeild.

BERKHAMPSTED SCHOOL, HERTS.

Twenty-eight miles from Euston. Good Scholarships and Exhibitions. Laboratory, heated swimming-bath, workshop, &c. £52 per annum.—Address, Head-Master.

NEW FORM OF HELIOSTAT

With specially strong and steady Clock-movement, 4 inches aperture.

Price from £10 10s. 0d. to £20.

SPECTROSCOPES

FOR THE OBSERVATORY OR LABORATORY,
FOR SOLAR, STELLAR, METEOR, RAINBAND, OR CHEMICAL RESEARCHES.

Of every Size and Description.

With prisms, either ordinary, simple and compound, with automatic adjustment to minimum deviation, or direct vision , or with gratings, flat or concave. All of the highest efficiency and workmanship

ADAM HILGER,
Astronomical and Optical Instrument Maker,
204 STANHOPE STREET, HAMPSTEAD ROAD, N.W.

TO SCIENCE CLASSES AND SCHOOLS.

MOORE BROTHERS have been placed upon the list of Traders from whom Specimens may be purchased, with the assistance of the Science and Art Department, and Specimens of their Work may be seen at South Kensington.

PRICE LISTS ON APPLICATION.

MOORE BROTHERS,
OSTEOLOGISTS, DISARTICULATORS, ETC.,
15 KREMLIN DRIVE, TUE BROOK, LIVERPOOL.
Awarded Seven Medals and Three Diplomas.

BEST BLACK INK KNOWN.

DRAPER'S INK (DICHROIC).

DIFFERING FROM ANYTHING ELSE EVER PRODUCED.

Writing becomes a pleasure when this Ink is used It has been adopted by the principal Banks, Public Offices, and Railway Companies throughout Ireland.

It writes almost instantly full Black.
Does not corrode Steel Pens.
Is cleanly to use, and not liable to Blot
Flows easily from the Pen
Blotting-paper may be applied at the moment of writing.

Can be obtained in London, through Messrs. BARCLAY & SONS, Farringdon Street; W. EDWARDS, Old Change ; F NEWBERY & SONS, Newgate Street ; and to be had of all Stationers.

BEWLEY & DRAPER (Limited), Dublin.

INVENTIONS EXHIBITION—GOLD MEDAL AWARDED.

DENT'S WATCHES.

TRADE MARK DENT

NEW ILLUSTRATED CATALOGUE of HIGH-CLASS WATCHES and CLOCKS at REDUCED PRICES, sent post free on application to E. DENT and Co., Makers to the Queen, 61 STRAND, LONDON, W.C., or 4 ROYAL EXCHANGE.

SECOND EDITION,
GRIFFIN'S
CHEMICAL HANDICRAFT.
PRICE 4s. 7d. POST FREE.

A CATALOGUE OF CHEMICAL APPARATUS;
ILLUSTRATED, CLASSIFIED, DESCRIPTIVE.
Demy 8vo, 480 pp., Illustrated with 1600 Woodcuts.
Most Complete and Cheapest List of Apparatus.

JOHN J. GRIFFIN AND SONS, 22 GARRICK STREET, LONDON, W.C.

PROJECTION POLARISCOPE,
Showing axes of Crystals, &c., on a well illuminated and flat field.

VAN HOUTEN'S
pure soluble COCOA
is the best and really the cheapest in the end.

The *British Medical Journal* says:—"'VAN HOUTEN'S COCOA' is admirable. In flavour it is perfect, and it is so pure, well prepared, and rich," &c., &c.

HOLLOWAYS OINTMENT AN INFALLIBLE REMEDY

For BAD LEGS, BAD BREASTS, OLD WOUNDS, SORES and ULCERS. If effectually rubbed on the Neck and Chest, it cures SORE THROATS, BRONCHITIS, COUGHS and COLDS; and for GOUT, RHEUMATISM, and all Skin Diseases it is unequalled.

JOHN LUCAS WALKER
STUDENTSHIP.

Applications for this Studentship, the holder of which "shall devote himself (or herself) to original research in Pathology," should be sent in on or before MAY 31, 1887, to Professor ROY, Trinity College, Cambridge, to whom also applications for further information regarding the Studentship may be addressed. The Studentship, which is of the annual value of £250, may be held by a person of either sex, and is tenable, subject to certain conditions, for three years.

Third Edition in a few days.
ADAPTED TO THE NEW BRITISH PHARMACOPŒIA, 1885.
Medium 8vo, price 21*s*.

A TEXT-BOOK OF PHARMACOLOGY, THERAPEUTICS, and MATERIA MEDICA.

By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S., Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; Late Examiner in the University of Edinburgh.

ADAPTED TO THE UNITED STATES PHARMACOPŒIA BY F. H. WILLIAMS, M.D., BOSTON, MASS.

"The work has little in common with the old-fashioned books on materia medica. . . . It is not a mere collection of dry facts and technical details, but a scientific treatise worthy to be ranked with the highest productions in physiology, either in our own or any other language. . . . It is a book of study for the scientist and a work of reference for the practical physician."—*Lancet.*

BY THE SAME AUTHOR.

DISORDERS OF DIGESTION: THEIR CONSEQUENCES AND TREATMENT.

This Work contains, in addition to the Lettsomian Lectures, a number of other Papers by the Author on similar subjects.
8vo, 10*s*. 6*d*.

"Distinguished by accurate observation and original thinking, these papers have been largely instrumental in moulding current medical opinion in regard to many of the subjects with which they are concerned."—*Edinburgh Medical Journal.*

"We can cordially recommend the volume, as one which combines much practical and technical information and sound common sense."—*London Medical Record.*

MACMILLAN & CO., LONDON.

LORD TENNYSON'S JUBILEE ODE.

MACMILLAN'S MAGAZINE,

No. 330, for APRIL, price 1*s*., contains:—

CARMEN SÆCULARE. By Lord TENNYSON. (An Ode in Honour of the Jubilee of Queen Victoria.)
THE WOODLANDERS. By THOMAS HARDY. Chapters XLIV.—XLVIII. (*Concluded.*)
WILLIAM HAZLITT. By GEORGE SAINTSBURY.
PERSIA. By J. D. REES.
"LADY CLANCARTY", AND THE HISTORICAL DRAMA. By MOWBRAY MORRIS.
HETH, a Romance of the Bush.
THE MAKING OF BRITAIN. By ARCHIBALD GEIKIE.

MACMILLAN & CO., LONDON.

MESSRS. MACMILLAN & CO.'S SCIENTIFIC WORKS.

NATURAL PHILOSOPHY.

A Text-Book of the Principles of Physics. By ALFRED DANIELL, M.A., LL.B., D.Sc., F.R.S.E., late Lecturer on Physics in the School of Medicine, Edinburgh. With Illustrations. Second Edition. Revised and Enlarged. Medium 8vo. 21s.

Elementary Practical Physics, Lessons in. By Professor BALFOUR STEWART, F.R.S., and W. W. HALDANE GEE, B.Sc. Crown 8vo.
Part I.—GENERAL PHYSICAL PROCESSES. 6s.
Part II.—ELECTRICITY AND MAGNETISM. [*Nearly ready.*
Part III.—OPTICS, HEAT, AND SOUND. [*In preparation.*

A School Course of Practical Physics. By the same Authors.
Part I.—ELECTRICITY AND MAGNETISM. [*In the press.*

Physics, Elementary Lessons in. By Professor BALFOUR STEWART, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d. (Questions on, 2s.)

Primer of Physics. By the same Author. With numerous Illustrations. New Edition, with Questions. 18mo. 1s. [*Science Primers.*

On Light. Being the Burnett Lectures, delivered in Aberdeen in 1883-1885. By GEORGE GABRIEL STOKES, M.A., P.R.S., &c., Fellow of Pembroke College, and Lucasian Professor of Mathematics in the University of Cambridge. First Course. ON THE NATURE OF LIGHT.—Second Course. ON LIGHT AS A MEANS OF INVESTIGATION. Crown 8vo. 2s. 6d. each.
THIRD COURSE. ON THE BENEFICIAL EFFECTS OF LIGHT. [*In the press.*

Spectrum Analysis. Lectures delivered in 1868 before the Society of Apothecaries of London. By Sir HENRY E. ROSCOE, LL.D., F.R.S., Professor of Chemistry in the Owens College, Victoria University, Manchester. Fourth Edition, revised and considerably enlarged by the Author and by ARTHUR SCHUSTER, F.R.S., Ph.D., Professor of Applied Mathematics in the Owens College, Victoria University. With Appendices, numerous Illustrations, and Plates. Medium 8vo. 21s.

Mechanical Theory of Heat. By R. Clausius. Translated by WALTER R. BROWNE, M.A., late Fellow of Trinity College, Cambridge. Crown 8vo. 10s. 6d.

Heat. By P. G. Tait, M.A., Sec. R.S.E., formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh. Crown 8vo. 6s.

Light: A Course of Experimental Optics, CHIEFLY WITH THE LANTERN. By LEWIS WRIGHT. With 200 Engravings and Coloured Plates. Crown 8vo. 7s. 6d.

Natural Philosophy for Beginners. By I. TODHUNTER, M.A., F.R.S. Fcap. 8vo. Part I.—The Properties of Solid and Fluid Bodies. With Illustrations. 3s. 6d. Part II.—Sound, Light, and Heat. 3s. 6d.

Electrostatics and Magnetism, Reprints of Papers on. By Sir WILLIAM THOMSON, D.C.L., LL.D., F.R.S., F.R.S.E., Fellow of St. Peter's College, Cambridge, and Professor of Natural Philosophy in the University of Glasgow. Second Edition. Medium 8vo. 18s.

Electricity and Magnetism. By Professor SILVANUS THOMPSON. With numerous Illustrations. Fcap. 8vo. 4s. 6d.

Electricity and Magnetism, Absolute MeaSUREMENTS IN. By Professor ANDREW GRAY, M.A., F.R.S.E. Pott 8vo. 3s. 6d.

Electric Light Arithmetic. By R. E. Day, M.A. Pott 8vo. 2s.

Heat and Electricity, A Collection of ExAMPLES ON. By H. H. TURNER, B.A., Fellow of Trinity College, Cambridge. Crown 8vo. 2s. 6d.

Steam, An Elementary Treatise on. By J. PERRY, C.E., Professor of Engineering in the Imperial College of Engineering, Yedo. With Illustrations, Numerical Examples, and Exercises. Fcap. 8vo. 4s. 6d.

Sound, Elementary Lessons on. By Dr. W. H. STONE. With Illustrations. Fcap. 8vo. 3s. 6d.

Units and Physical Constants. By J. D. EVERETT, M.A., D.C.L., F.R.S., F.R.S.E., Professor of Natural Philosophy, Queen's College, Belfast. Second Edition. Globe 8vo. 5s.

Applied Mechanics: An Elementary General Introduction to the Theory of Structures and Machines. By JAMES H. COTTERILL, F.R.S., Associate Member of the Council of the Institution of Naval Architects, Associate Member of the Institution of Civil Engineers, Professor of Applied Mechanics in the Royal Naval College, Greenwich. Medium 8vo. 18s.

NATURAL PHILOSOPHY—*Continued.*

The Kinematics of Machinery. Outlines of a Theory of Machines. By Professor F. REULEAUX. Translated and Edited by Professor A. B. W. KENNEDY, C.E. With 450 Illustrations. Medium 8vo. 21s.

The Mechanics of Machinery. By A. B. W. KENNEDY, M.Inst.C.E., Professor of Engineering and Mechanical Technology in University College, London. With numerous Illustrations. Crown 8vo. 12s. 6d.

Elementary Science, Numerical Tables and CONSTANTS IN. By SYDNEY LUPTON, M.A., F.C.S., F.I.C. Globe 8vo. 2s. 6d.

Chemical Arithmetic. With 1200 Examples. By the same Author. Second Edition. Globe 8vo. 4s. 6d.

ASTRONOMY.

Popular Astronomy. By S. Newcomb, LL.D., Professor U.S. Naval Observatory. With 112 Illustrations and 5 Maps of the Stars. Second Edition, revised. 8vo. 18s.

Popular Astronomy. By Sir G. B. Airy, K.C.B., F.R.S., late Astronomer-Royal. With numerous Illustrations. Fcap. 8vo. 4s. 6d.

Astronomy, Elementary Lessons in. By J. NORMAN LOCKYER, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 5s. 6d. (Questions on, 1s. 6d.)

The Chemistry of the Sun. By J. Norman LOCKYER, F.R.S. With Illustrations. Demy 8vo. 14s.

Primer of Astronomy. By J. Norman LOCKYER, F.R.S. With numerous Illustrations. New Edition. 18mo. 1s. [*Science Primers.*

CHEMISTRY.

Inorganic and Organic Chemistry. A Complete Treatise on Inorganic and Organic Chemistry. By Sir HENRY E. ROSCOE, F.R.S., and Professor C. SCHORLEMMER, F.R.S. With numerous Illustrations. Medium 8vo.
Vols. I. and II.—INORGANIC CHEMISTRY.
Vol. I.—The Non-Metallic Elements. 21s. Vol. II. Part I.—Metals. 18s. Vol. II. Part II.—Metals. 18s.
Vol. III.—ORGANIC CHEMISTRY. Three Parts. The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. With numerous Illustrations. Medium 8vo. Parts I. and II., 21s. each. Part III., 18s.

Elements of Chemical Physics. By Josiah P. COOKE, Jun., Erving Professor of Chemistry and Mineralogy in Harvard University. Fourth Edition. Royal 8vo. 21s.

A Manual of the Chemistry of the Carbon COMPOUNDS, OR ORGANIC CHEMISTRY. By C. SCHORLEMMER, F.R.S., Professor of Chemistry in the Victoria University, the Owens College, Manchester. With Illustrations. 8vo. 14s.

The Elements of Thermal Chemistry. By M. M. PATTISON MUIR, M.A., F.R.S.E., Fellow and Prælector of Chemistry in Gonville and Caius College, Cambridge, Assisted by DAVID MUIR WILSON. 8vo. 12s. 6d.

The Study of Chemistry, an Introduction TO. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

Compounds of Carbon; or, Organic Chemistry, an Introduction to the Study of. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

Chemistry, Elementary Lessons in. By Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d. Problems adapted to the same, by Professor THORPE. With Key. 18mo. 2s.

Owen's College Junior Course of Practical CHEMISTRY. By F. JONES. With Preface by Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 2s. 6d.

Questions on Chemistry. A Series of Problems and Exercises in Inorganic and Organic Chemistry. By F. JONES, F.R.S.E., F.C.S. Fcap. 8vo. 3s.

Primer of Chemistry. By Sir Henry E. ROSCOE, F.R.S. With numerous Illustrations. New Edition. With Questions. 18mo. 1s. [*Science Primers.*

Chemical Theory, Experimental Proofs of, FOR BEGINNERS. By WILLIAM RAMSAY, Ph.D. Fcap. 8vo. 2s. 6d.

MACMILLAN & CO., LONDON.

PUBLISHED BY J. & A. CHURCHILL.

No. CVIII. (MARCH), with Ten Lithographic Plates (Plain and Coloured), Price 10s.

THE QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE.

Edited by E. RAY LANKESTER, M.A., LL.D., F.R.S., Fellow of Exeter College, Oxford, and Jodrell Professor of Zoology in University College, London.

With the co-operation of W. T. THISELTON DYER, M.A., C.M.G., F.R.S., Director of the Royal Gardens, Kew; E. KLEIN, M.D., F.R.S., Joint-Lecturer on General Anatomy and Physiology in the Medical School of St. Bartholomew's Hospital, London. H. N. MOSELEY, M.A., LL.D., F.R.S., Linacre Professor of Human and Comparative Anatomy in the University of Oxford; and ADAM SEDGWICK, M.A., F.R.S., Fellow and Assistant Lecturer of Trinity College, Cambridge.

CONTENTS:—

The Termination of Nerves in the Liver. By A. B. MACALLUM, B.A., Fellow of University College, Toronto, Canada.

On the Nuclei of the Striated Muscle-Fibre in *Necturus* (*Menobranchus*) *lateralis*. By A. B. MACALLUM, B.A., Fellow of University College, Toronto, Canada.

The Development of the Cape Species of Peripatus. Part III. On the Changes from Stage A to Stage F. By ADAM SEDGWICK, M.A., F.R.S., Fellow of Trinity College, Cambridge.

Morphological and Biological Observations on *Criodrilus lacuum*, Hoffmeister. By Dr. L. ORLEY, Zoolog. Instit. University of Budapest.

Studies on Earthworms. No. III. *Criodrilus lacuum*, Hoffmeister. By WILLIAM BLAXLAND BENHAM, B.Sc., Demonstrator in the Zoological Laboratory of University College, London.

Notes on the Chromatology of *Anthea cereus*. By C. A. MACMUNN, M.A., M.D.

On *Ctenodrilus parvulus*, nov. sp. By ROBERT SCHARFF, B.Sc., Ph.D.

The Relation of the Nemertea to the Vertebrata. By A. A. W. HUBRECHT, Professor in Utrecht.

Fifth Edition, Revised and Enlarged, with 90 Engravings, 8vo, 16s.

SUTTON'S HAND-BOOK OF VOLUMETRIC ANALYSIS; or,

the Quantitative Estimation of Chemical Substances by Measure, applied to Liquids, Solids, and Gases. Adapted to the Requirements of Pure Chemical Research, Pathological Chemistry, Pharmacy, Metallurgy, Manufacturing Chemistry, Photography, &c., and for the Valuation of Substances used in Commerce, Agriculture, and the Arts.

Vol. II., Second Edition, Revised and Enlarged, 8vo, 17s. 6d.

COMMERCIAL ORGANIC ANALYSIS. By ALFRED H. ALLEN, F.I.C., F.C.S.

CONTENTS:—Fixed Oils, Lard, Tallow, Butter, Waxes, Lubricating Oils, Fatty Acids, Soaps, Glycerin, Hydrocarbons, Shale Oil, Coal Tar, Asphalt, Petroleum, Kerosene, Paraffin, Essential Oils, Turpentine, Resins, Rosin Oil, Benzols and Naphthas, Naphthalene, Anthracene, Carbolic Acid, Carbolic Powders, Creosote Oils, Creosote, &c., &c.

Vol. I. (price 14s.) contains Alcohols, Ethers, and other Neutral Alcoholic Derivatives, Sugars, Starch and its Isomers, Vegetable Acids, &c., &c.

Vol. III., completing the work, is in preparation.

VALENTIN'S QUALITATIVE ANALYSIS. Revised and Corrected

by Dr. W. R. HODGINSON, F.R.S.E., F.I.C., Professor of Chemistry and Physics, Royal Military Academy, and H. M. CHAPMAN, Assistant-Demonstrator of Chemistry in the Royal School of Mines, South Kensington. Sixth Edition, with Engravings, 8vo, 8s. 6d.

PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC

ANALYSIS, specially adapted for Colleges and Schools. By FRANK CLOWES, D.Sc., Professor of Chemistry in University College, Nottingham. Fourth Edition, with 55 Engravings, post 8vo, 7s. 6d.

A MEDICAL HAND-BOOK; comprehending such Information on

Medical and Sanitary Subjects as is desirable in Educated Persons. By FREDERICK W. HEADLAND, M.D., F.R.C.P. Fcap. 8vo, 5s.

A MANUAL OF ANIMAL VACCINATION; preceded by Consider-

ations on Vaccination in General. By Dr. E. WARLOMONT, Founder of the State Vaccine Institute of Belgium, Director of the "Institut Vaccinal de Belgique" at Brussels, &c. Translated and Edited by ARTHUR J. HARRIES, M.D., Senior Assistant-Physician to St. John's Hospital for Diseases of the Skin, Consulting Physician to the Association for the Supply of Pure Vaccine Lymph. With Illustrations. Crown 8vo, 4s. 6d.

OUTLINES OF ORGANIC CHEMISTRY. By H. FORSTER MORLEY,

M.A., D.Sc., Fellow of, and Assistant Professor of Chemistry at, University College, London. Crown 8vo, 7s. 6d.

THE MICROTOMIST'S VADE-MECUM, comprising upwards of 600

Formulæ and Methods, collected from the practice of the best workers. By ARTHUR BOLLES LEE. Crown 8vo, 8s. 6d.

AN INTRODUCTION TO PHYSICAL MEASUREMENTS; with

Appendices on Absolute Electrical Measurement, &c. By Dr. F. KOHLRAUSCH, Professor in the University of Wurzburg. Translated Edition by T. H. WALLER, B.A., B.Sc., and H. R. PROCTER, F.C.S. Second Edition, with 37 Engravings, 8vo, 15s.

CHURCHILL'S TECHNOLOGICAL HAND-BOOKS. Edited by

JOHN GARDNER, F.I.C., F.C.S., and JAMES CAMERON, F.I.C., Analyst in the Laboratory, Somerset House.

BREWING, DISTILLING, and WINE MANUFACTURE. With Engravings. Crown 8vo, 6s. 6d.
BLEACHING, DYEING, and CALICO PRINTING. With Engravings. Crown 8vo, 5s.
ACETIC ACID and VINEGAR, AMMONIA, and ALUM. With Engravings. Crown 8vo, 5s.
OILS and VARNISHES. With Engravings. Crown 8vo, 7s. 6d.

⁂ *Other Works in preparation.*

GOLD MEDAL,
International Inventions Exhibition, 1885.

Now Ready, Vol. VIII., Part I.

THE JOURNAL OF PHYSIOLOGY.

Edited, with the Co-operation in England of Prof. W. RUTHERFORD, F.R.S., of Edinburgh, Prof. J. BURDON-SANDERSON, F.R.S., of Oxford; and in America of Prof. H. P. BOWDITCH, of Boston; Prof. H. NEWELL MARTIN, F.R.S., of Baltimore; Prof H C. WOOD, of Philadelphia,

BY MICHAEL FOSTER, M.D., F.R.S.

SEISMOGRAPHS
From the Designs of Prof. J. A. EWING.
A fully-illustrated Description will be sent on application.

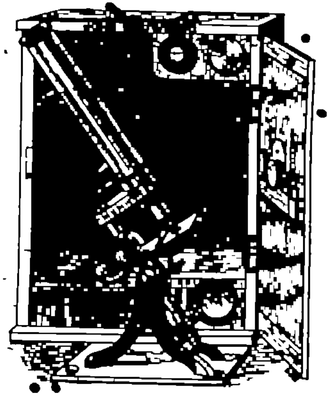
A DESCRIPTIVE LIST
OF
ANTHROPOMETRIC APPARATUS,
CONSISTING OF
INSTRUMENTS FOR MEASURING AND TESTING THE CHIEF PHYSICAL CHARACTERISTICS OF THE HUMAN BODY.

Designed under the direction of Mr. FRANCIS GALTON, and Manufactured and Sold by

THE CAMBRIDGE SCIENTIFIC INSTRUMENT COMPANY,
ST. TIBB'S ROW, CAMBRIDGE, ENGLAND.

The Company are appointed Agents for the Microscopes of Zeiss, a supply of which is kept in stock.

BROWNING'S
"PERFECT"



MICROSCOPE.

The body is made entirely of brass and gun-metal, with rack-motion and fine screw adjustment. Three achromatic powers of excellent defining power, 1-inch, ½-inch and ¼-inch; adjusting slide-holder to stage, revolving diaphragm, hand-forceps, stage-forceps, live-cage, &c. The whole packed in upright Mahogany Cabinet, with drawer for slides, dissecting-knives, &c.

PRICE £3 15s. 0d.

JOHN BROWNING, 63 STRAND, LONDON, W.C.

A New Edition is now Ready.

EVENING LECTURES TO WORKING MEN.

NORMAL SCHOOL OF SCIENCE AND ROYAL SCHOOL OF MINES.

The Third Course, consisting of Six Lectures on MECHANISM, by Dr A R. WILLIS, M A, will be delivered at the Museum of Practical Geology in Jermyn Street, S.W, commencing at 8 o'clock on Monday Evening, April 16, 1887. Tickets may be obtained by Working Men only on application at the Museum on Tuesday Evening, April 12. Fee for the Course, 6d. Each Applicant is requested to bring his Name, Address, and Occupation, written on a piece of paper, for which the Ticket will be exchanged.

UNIVERSITY COLLEGE, LONDON.

ADVANCED INORGANIC CHEMISTRY.

DR. S. RIDEAL will give a Course of Thirty Lectures on Mondays, Wednesdays, and Fridays, at 4 p m, commencing APRIL 22. The Course is fitted for Students reading for Honours in Chemistry at the University of London July Examinations. Recent Progress in Physical Chemistry and the Study of the Rarer Elements form part of the Course. Fee, £4 4s.

J. M. HORSBURGH, M.A., Secretary.

UNIVERSITY COLLEGE, LONDON.

ORGANIC CHEMISTRY.

Assistant-Professor, H. FORSTER MORLEY, M.A., D.Sc.

The following Courses of Lectures will be given in May, June, and July:—(a) *Elementary*, Tuesdays, Wednesdays, and Fridays, at 11; (b) *Special Course*, including subjects required by Candidates for Int. M.B. (Three Lectures a Week); (c) *Advanced*, including the more important results of Recent Research in Organic Chemistry, and in the Study of the Physical Constants of Organic Bodies (Two Lectures a Week). Dates of beginning. (a) May 3; (b) May 4, at 9 a.m.; (c) April 19, at 9 a.m.

J. M. HORSBURGH, M.A., Secretary.

UNIVERSITY COLLEGE, LONDON.

The PROFESSORSHIP of CHEMISTRY will be Vacant at the end of the present Session by the resignation of Prof. A. W. WILLIAMSON, F.R.S. Applications should be sent in not later than APRIL 30 to the SECRETARY of the College, from whom information may be obtained as to the Duties and Emoluments of the Professorship.

J. M. HORSBURGH, M.A., Secretary.

PRELIMINARY SCIENTIFIC EXAMINATION.

UNIVERSITY OF LONDON.

A Special Course of Lectures and Practical Work (four afternoons a week) "On Biology (Animal Portion)," under the Direction of Prof. RAY LANKESTER, will be given at University College, London, during the Summer Session, adapted to the requirements of Candidates for the above Examination. To commence MAY 5.

A Course of Lectures will also be given by Dr. R. VON LENDENFELD, Assistant in the Zoological Laboratory of University College, on "Parasitic Worms," commencing on the same day, and adapted to the requirements of Students of Medicine and Zoology.

For further particulars, apply to the SECRETARY University College, London.

Prof. HENRICI, F.R.S., will Deliver a

Course of Eight Lectures "On the Method of Least Squares, with Applications to Physical and Chemical Problems," on Mondays from 5 to 6 p.m., commencing on MONDAY, MAY 2, at the Central Institution of the City and Guilds of London Institute. A Previous Knowledge of the Differential Calculus will not be necessary. Fee for the Course, Ten Shillings. For Syllabus, apply at Central Institution, Exhibition Road, S.W.

PHILIP MAGNUS, Director and Secretary.

KING'S COLLEGE, LONDON.

BACTERIOLOGY.

A Practical Course will be given in the Physiological Laboratory for four days a week, from 2 to 4.30, by E. CROOKSHANK, M B. The Class will meet on May 17, and last for three weeks.

For Syllabus and further information, apply to

J. W. CUNNINGHAM, Secretary.

GUY'S HOSPITAL MEDICAL SCHOOL.

UNIVERSITY OF LONDON, PRELIMINARY SCIENTIFIC (M.B.) EXAMINATION.

Instruction is given in all the subjects of the above Examination at GUY'S HOSPITAL during the Winter and Summer Sessions. The Fee for the whole Course is 10 Guineas. The Class is not confined to Students of the Hospital.

For further particulars, apply to the DEAN, Guy's Hospital, Southwark, S.E.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to

THOMAS BOLTON, 57 NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers the Nymph of Leptophlebia (marginata?), with sketch and description. He also sent out Freshwater Mussel Spat, Salmon Fry, Lophopus crystallinus, Philodina roseola, Stephanoceros Eichhornii, Volvox globator, Vaucheria, Zygnema; also Hydra, Amoeba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s. or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

LONDON HOSPITAL AND MEDICAL COLLEGE,

MILE-END, E.

The SUMMER SESSION will commence on MONDAY, May 2.

The New College Buildings are now complete, and afford more than double the former accommodation.

Intending Students are advised that, under the new regulations of the Examining Board in England, it is exceedingly advantageous to enter for the Summer Session. Students now entering are also eligible for the Entrance Scholarships in September.

The Hospital contains nearly 800 beds, and is the largest General Hospital in Great Britain.

General Fee for Lectures and Hospital Practice, 90 guineas in one sum, or 100 guineas in three instalments. The Resident and other Hospital Appointments are free to full Students.

Special entries may be made for Medical and Surgical Practice, also for the course of Practical Surgery.

The London Hospital is now in direct communication by rail and tram with all parts of the Metropolis, and the Metropolitan, Metropolitan District, South-Eastern, and East London Railways have stations within a minute's walk of the Hospital and College.

For Prospectus and particulars apply to

MUNRO SCOTT, Warden.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, S.E.

The SUMMER SESSION will commence on May 2. Students entering in the summer are eligible to compete for the Science Scholarships of 125 Guineas and £60 awarded in October.

There are numerous Prizes and Scholarships, and all Appointments are open to Students without extra charge.

Special Classes for the Examinations of the University of London are held throughout the year. A Register of Approved Lodgings and of Private Families receiving Students to reside is kept in the Secretary's Office.

Prospectus and all particulars can be obtained from the Medical Secretary, Mr. G. RENDLE.

W. M. ORD, Dean.

EAST GRINSTEAD COLLEGIATE SCHOOL,

MAYPOLE ROAD, SUSSEX.

The object of the School is to afford a Sound Education, which will fit boys for either Professional or Commercial life. Most careful attention is paid to the requirements of boys intended for commercial pursuits. Boys are received from seven to fourteen years of age. There is a Junior Class, specially adapted to prepare the younger boys for the work of the higher classes. Each pupil will receive careful attention, especially in those subjects wherein he is weak. No injurious cramming encouraged. The course of Instruction includes all the subjects required at the various public examinations. The Principal has had many years' experience in good schools, and has proved himself a most successful Master. The Fees are moderate.—For Prospectus and particulars, apply to the PRINCIPAL.

AGRICULTURAL COLLEGIATE SCHOOL,

EAST GRINSTEAD, SUSSEX.

For Sons of Gentlemen, from seven years of age. The Course of Studies or Instruction is designed to prepare boys to occupy the positions of Landowners, Land Agents, Farmers, intending Colonists, &c. It provides full instruction in the practice and science of Agriculture and Estate Management, Management of Live Stock, Dairy Farming, Agricultural Chemistry, &c. Pupils are prepared for all the Examinations.

The College offers the following advantages:—A most superior education. A Staff of Masters selected for their qualifications as Scholars and their tried ability as Teachers. A Boarding Department carefully supervised and excellently appointed, its diet liberal, and all arrangements calculated to develop gentlemanly habits, and to produce feelings of self-respect.

The strictest attention to the moral and religious training of Pupils. Fees most moderate. References of high character to Parents of Pupils.

Prospectus and all particulars on application to the PRINCIPAL.

As CURATOR or ASSISTANT in a Natural History Museum or Library, or as Secretary to a Gentleman. - Botanist (more particularly), Entomologist, Conchologist, and Ornithologist. Has much experience in Mounting and Arranging Specimens of various kinds. Writes a very neat hand.—Apply to Rev. Dr. CHURCHILL BABINGTON, F.L.S., Cockfield Rectory, R.S.O., Suffolk.

BIOLOGY AND PHYSICS.—Coaching for Prelim Sci. and B.Sc. by former Demonstrator. Over 50 Successes.—G. WILLIAM HILL, M.D., B Sc Lond., 37 Cornwall Road, W.

A FRENCH GENTLEMAN, with First-rate Scholastic Recommendations, has a French Class for Army Pupils at 2 Colville Gardens, Bayswater. He and his wife also receive as Boarders two or three Young Men who wish to study the language for business or conversational purposes.—Address M. ALFRED VIGIER, Swanley, Kent.

BERKHAMPSTED SCHOOL, HERTS.
Twenty-eight miles from Euston. Good Scholarships and Exhibitions. Laboratory, heated swimming-bath, workshop, &c. £52 per annum.—Address, Head-Master.

MUSEUMS AND COLLECTORS.

MR. DAMON, of WEYMOUTH, will forward an abridged Catalogue of his Collections in Natural History Objects, including RECENT SHELLS (Foreign and British), FOSSIL REMAINS, MINERALS, ROCKS, MARINE ZOOLOGY, &c., &c., &c.

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1s. per bottle, with full instructions for use, from most Opticians. Post free for 1s. 3d. from

EDWARD WARD, 249 Oxford Street, Manchester. [503

NATURALISTS' GLASS-CAPPED BOXES.

Museums and Private Collectors supplied with Round and Rectangular Glass-capped Boxes from One Shilling per dozen. About 70 different sizes always in Stock. A cheap Glazed Box, 14 inches by 10 inches, for One Shilling. Samples Post Free, Two Shillings.

THOMAS D. RUSSELL,
PRIZE MEDALLIST, HEALTH EXHIBITION.
78 NEWGATE STREET, LONDON, E.C.

TO SCIENCE CLASSES AND SCHOOLS.

MOORE BROTHERS have been placed upon the list of Traders from whom Specimens may be purchased, with the assistance of the Science and Art Department, and Specimens of their Work may be seen at South Kensington.

PRICE LISTS ON APPLICATION

MOORE BROTHERS,
OSTEOLOGISTS, DISARTICULATORS, ETC.,
15 KREMLIN DRIVE, TUE BROOK, LIVERPOOL.
Awarded Seven Medals and Three Diplomas.

Excellent Copies of the **actual, natural Handwriting,** also of **Drawings, Music,** even of **elaborate Sketches, Programmes, Plans** (up to Double-Elephant size), **Shorthand,** and **Type-Writing** are easily, quickly, and cheaply produced by the

AUTOCOPYIST

Very fluid Ink, used with ordinary pen and paper. Auto-Circulars resemble *written* letters. Used at the House of Lords, &c.

AUTOCOPYIST CO.,
72 London Wall, London, and 52 Princess Street, Manchester.

Sale by Auction.

SALE OF A NATURAL HISTORY COLLECTION IN COPENHAGEN.

ON WEDNESDAY, APRIL 20, 1887, at 10 a.m. and 5 p.m., and following Days, will be Sold the Natural History Collections of the late R. CONRADSON, Conservator, consisting of MAMMALS, BIRDS, REPTILES, and FISHES, partly mounted, partly in the skin, and partly in spirits. Also, Articulata and Mollusks in spirits, and Collections of Eggs, &c. In these Collections the following are specially to be noted:—Rare Skins of Mammals and Birds from New Holland, Samoa Islands, Java, &c., and a valuable Collection of Works on Natural History.

All the above will be Sold by Auction at the Hotel Phönix, Dronningens Tværgade, N.1.

The Books will be sold at 5 p.m. on April 20.

The above Collections will be on view on April 18 and 19, from 11 a.m. to 5 p.m., at Bredgade No. 35.

Catalogues may be had from Advocat KLUBIEN, Bredgade No. 43, to whom payment is to be made.

Messrs LYNGE, of Walkendorfsgade 8, and KLEIN, of Pilestræde 40, Booksellers, will receive Commissions.

ROCKS, MINERALS, FOSSILS.
F. H. BUTLER,
Assoc. R. S. Mines Lond., M.A. Oxon., L.S.A. Lond., &c.,
Successor to the late R. TALLING,
180 BROMPTON ROAD, LONDON, S.W.

A limited number of the recently described Cornish CRYSTALLISED DUFRENITE, new to Great Britain, in stock, also a fresh series of foreign and Scotch rocks and rock-sections. The Pelecypoda and Echinodermata of the Wright Collection, now fully arranged, on view.

MINERALOGY AND GEOLOGY.

CHOICE SPECIMENS FOR MUSEUMS AND PRIVATE COLLECTORS: BERYLS, TOPAZES, RUTILES ON MATRIX, CELESTINE, OPALS, &c., &c.

RARE MINERALS FOR SCIENTIFIC RESEARCH; COLLECTIONS FOR STUDENTS AND PROSPECTORS.

VERY FINE POLISHED SECTIONS OF AMMONITES AND NAUTILI.

NEW SERIES OF ROCKS. MICROSCOPIC SLIDES.

Hammers, Chisels, and Blow-pipe Apparatus.

PRIVATE LESSONS AND EVENING CLASSES.

CATALOGUES ON APPLICATION.

SAMUEL HENSON,
277 STRAND, LONDON,
Opposite Norfolk Street.

SIX PRIZE MEDALS
AWARDED FOR GEOLOGICAL COLLECTIONS.
Geological Collection especially adapted for Teaching as supplied to Science and Art Department, and used by all Lecturers and Teachers in Great Britain, &c.
New and Rare Minerals constantly arriving from all parts for selection of Single Specimens.
ROCK SECTIONS AND ROCK SPECIMENS:
The Largest Variety in England.
New Catalogues and Lists on application to—

A CATALOGUE OF CHEMICAL APPARATUS;

ILLUSTRATED, CLASSIFIED, DESCRIPTIVE

Demy 8vo, 480 pp., Illustrated with 1600 Woodcuts.

Most Complete and Cheapest List of Apparatus.

JOHN J. GRIFFIN AND SONS, 22 GARRICK STREET, LONDON, W.C.

HOLLOWAY'S PILLS THIS MEDICINE

Is a Certain Cure for all Disorders of the LIVER, STOMACH AND BOWELS. A Great PURIFIER of the BLOOD; a Powerful Invigorator of the System, in cases of WEAKNESS AND DEBILITY, and is unequalled in Female Complaints.

NEW FORM OF HELIOSTAT

With specially strong and steady Clock-movement, 4 inches aperture.

Price from £10 10s. 0d. to £20.

SPECTROSCOPES

FOR THE OBSERVATORY OR LABORATORY,
FOR SOLAR, STELLAR, METEOR, RAINBAND, OR CHEMICAL RESEARCHES.

Of every Size and Description.

With prisms, either ordinary, simple and compound, with automatic adjustment to minimum deviation, or direct vision, or with gratings, flat or concave. All of the highest efficiency and workmanship.

ADAM HILGER,
Astronomical and Optical Instrument Maker,
204 STANHOPE STREET, HAMPSTEAD ROAD, N.W.

WOOD'S

MAGIC LANTERNS & SLIDES.

THE LARGEST AND BEST STOCK IN THE KINGDOM.

ON SALE OR HIRE.

The "EUPHANERON" LANTERN," with the Four-wick Lamp,

Is unsurpassed for power, portability, and price, £4 4s.

SPECIAL ATTENTION *is called to the great advantages offered to Hirers of Slides by Wood's £2 2s. Yearly Subscription, and also to the very favourable terms upon which Slides purchased of E. G. Wood may be exchanged. Full particulars will be found in Wood's New List of Slides and Lanterns. Post free for One Stamp.*

NATURAL PHILOSOPHY.

A Text-Book of the Principles of Physics. By ALFRED DANIELL, M.A., LL.B., D.Sc., F.R.S.E., late Lecturer on Physics in the School of Medicine, Edinburgh. With Illustrations. Second Edition. Revised and Enlarged. Medium 8vo. 21s.

Elementary Practical Physics, Lessons in. By Professor BALFOUR STEWART, F.R.S., and W. W. HALDANE GEE, B Sc. Crown 8vo.
Part I.—GENERAL PHYSICAL PROCESSES 6s.
Part II.—ELECTRICITY AND MAGNETISM. [*Nearly ready.*
Part III.—OPTICS, HEAT, AND SOUND. [*In preparation.*

A School Course of Practical Physics. By the same Authors.
Part I.—ELECTRICITY AND MAGNETISM. [*In the press.*

Physics, Elementary Lessons in. By Professor BALFOUR STEWART, F R.S. New Edition. With numerous Illustrations Fcap. 8vo 4s. 6d. (Questions on, 2s)

Primer of Physics. By the same Author. With numerous Illustrations. New Edition, with Questions. 18mo. 1s [*Science Primers.*

On Light. Being the Burnett Lectures, delivered in Aberdeen in 1883-1885. By GEORGE GABRIEL STOKES, M.A., P.R.S., &c., Fellow of Pembroke College, and Lucasian Professor of Mathematics in the University of Cambridge. First Course. ON THE NATURE OF LIGHT.—Second Course. ON LIGHT AS A MEANS OF INVESTIGATION. Crown 8vo. 2s. 6d. each.
THIRD COURSE. ON THE BENEFICIAL EFFECTS OF LIGHT. [*In the press.*

Spectrum Analysis. Lectures delivered in 1868 before the Society of Apothecaries of London. By Sir HENRY E. ROSCOE, LL.D , F.R.S , Professor of Chemistry in the Owens College, Victoria University, Manchester. Fourth Edition, revised and considerably enlarged by the Author and by ARTHUR SCHUSTER, F.R.S., Ph D., Professor of Applied Mathematics in the Owens College, Victoria University. With Appendices, numerous Illustrations, and Plates. Medium 8vo. 21s.

Mechanical Theory of Heat. By R. Clausius. Translated by WALTER R. BROWNE, M.A., late Fellow of Trinity College, Cambridge. Crown 8vo. 10s. 6d.

Heat. By P. G. Tait, M.A., Sec. R.S.E., formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh. Crown 8vo 6s.

Light: A Course of Experimental Optics, CHIEFLY WITH THE LANTERN. By LEWIS WRIGHT. With 200 Engravings and Coloured Plates Crown 8vo. 7s. 6d.

Natural Philosophy for Beginners. By I. TODHUNTER, M.A , F.R.S. Fcap. 8vo. Part I.—The Properties of Solid and Fluid Bodies. With Illustrations. 3s. 6d. Part II.—Sound, Light, and Heat. 3s. 6d.

Electrostatics and Magnetism Reprints of Papers on By Sir WILLIAM THOMSON, D.C.L., LL.D., F R S., F.R.S.E., Fellow of St. Peter's College, Cambridge, and Professor of Natural Philosophy in the University of Glasgow. Second Edition. Medium 8vo. 18s

Electricity and Magnetism. By Professor SILVANUS THOMPSON. With numerous Illustrations. Fcap 8vo. 4s. 6d.

Electricity and Magnetism, Absolute MeaSUREMENTS IN. By Professor ANDREW GRAY, M.A., F.R.S.E Pott 8vo. 3s. 6d.

Electric Light Arithmetic By R. E. Day, M.A. Pott 8vo. 2s

Heat and Electricity, A Collection of ExAMPLES ON. By H. H. TURNER, B A , Fellow of Trinity College, Cambridge. Crown 8vo. 2s. 6d.

Steam, An Elementary Treatise on. By J. PERRY, C E., Professor of Engineering in the Imperial College of Engineering, Yedo. With Illustrations, Numerical Examples, and Exercises. Fcap. 8vo 4s 6d.

Sound, Elementary Lessons on. By Dr. W. H. STONE. With Illustrations. Fcap. 8vo. 3s. 6d.

Units and Physical Constants. By J. D. EVERETT, M.A., D C.L., F R.S., F.R.S.E , Professor of Natural Philosophy, Queen's College, Belfast. Second Edition. Globe 8vo. 5s.

Applied Mechanics : An Elementary General Introduction to the Theory of Structures and Machines By JAMES H. COTTERILL, F.R.S., Associate Member of the Council of the Institution of Naval Architects, Associate Member of the Institution of Civil Engineers, Professor of Applied Mechanics in the Royal Naval College, Greenwich. Medium 8vo. 18s.

NATURAL PHILOSOPHY—*Continued.*

The Kinematics of Machinery. Outlines of a Theory of Machines. By Professor F. REULEAUX. Translated and Edited by Professor A. B. W. KENNEDY, C.E. With 450 Illustrations. Medium 8vo. 21s.

The Mechanics of Machinery. By A. B. W. KENNEDY, M Inst.C E., Professor of Engineering and Mechanical Technology in University College, London. With numerous Illustrations. Crown 8vo. 12s. 6d.

Elementary Science, Numerical Tables and CONSTANTS IN. By SYDNEY LUPTON, M.A., F.C.S., F.C I. Globe 8vo. 2s. 6d.

Chemical Arithmetic. With 1200 Examples. By the same Author. Second Edition. Globe 8vo. 4s. 6d.

ASTRONOMY.

Popular Astronomy. By S. Newcomb, LL.D.; Professor U.S. Naval Observatory. With 112 Illustrations and 5 Maps of the Stars. Second Edition, revised. 8vo. 18s.

Popular Astronomy. By Sir G. B. Airy, K.C.B., F.R.S., late Astronomer-Royal. With numerous Illustrations. Fcap. 8vo. 4s 6d.

Astronomy, Elementary Lessons in. By J. NORMAN LOCKYER, F.R.S. New Edition. With numerous Illustrations. Fcap 8vo. 5s 6d. (Questions on, 1s. 6d)

The Chemistry of the Sun. By J. Norman LOCKYER, F.R.S. With Illustrations. Demy 8vo 14s.

Primer of Astronomy. By J. Norman LOCKYER, F.R.S. With numerous Illustrations. New Edition. 18mo. 1s. [*Science Primers.*

CHEMISTRY.

Inorganic and Organic Chemistry. A Complete Treatise on Inorganic and Organic Chemistry. By Sir HENRY E. ROSCOE, F.R.S , and Professor C. SCHORLEMMER, F.R S. With numerous Illustrations. Medium 8vo
Vols. I. and II.—INORGANIC CHEMISTRY.
Vol. I.—The Non-Metallic Elements. 21s. Vol. II. Part I.—Metals 18s. Vol. II. Part II.—Metals 18s
Vol. III.—ORGANIC CHEMISTRY. Three Parts.
The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. With numerous Illustrations. Medium 8vo. Parts I. and II., 21s each. Part III., 18s.

Elements of Chemical Physics. By Josiah P. COOKE, Junr., Erving Professor of Chemistry and Mineralogy in Harvard University. Fourth Edition. Royal 8vo. 21s.

A Manual of the Chemistry of the Carbon COMPOUNDS, OR ORGANIC CHEMISTRY. By C. SCHORLEMMER, F R.S., Professor of Chemistry in the Victoria University, the Owens College, Manchester. With Illustrations. 8vo 14s.

The Elements of Thermal Chemistry. By M. M. PATTISON MUIR, M A., F.R.S E , Fellow and Prælector of Chemistry in Gonville and Caius College, Cambridge, Assisted by DAVID MUIR WILSON. 8vo. 12s. 6d.

The Study of Chemistry, an Introduction TO. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

Compounds of Carbon; or, Organic Chemistry, an Introduction to the Study of. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

Chemistry, Elementary Lessons in. By Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations Fcap 8vo. 4s. 6d Problems adapted to the same, by Professor THORPE. With Key 18mo. 2s.

Owens College Junior Course of Practical CHEMISTRY. By F. JONES. With Preface by Sir HENRY E. ROSCOE, F R.S. New Edition. With numerous Illustrations Fcap. 8vo. 2s. 6d.

Questions on Chemistry. A Series of Problems and Exercises in Inorganic and Organic Chemistry. By F. JONES, F.R.S.E., F.C.S. Fcap 8vo. [illegible]

Primer of Chemistry. By Sir Henry E. ROSCOE, F.R S. With numerous Illustrations. New Edition With Questions. 18mo. 1s. [*Science Primers*

A TREATISE ON ORE DEPOSITS. By J. ARTHUR PHILLIPS, F.R.S., V.P.G.S., F.C.S., M.Inst.C.E., Ancien Elève de l'Ecole des Mines, Paris; Author of "A Manual of Metallurgy," "The Mining and Metallurgy of Gold and Silver," &c. With numerous Illustrations 8vo 25s.

GEOGRAPHY.

CLASS-BOOK OF GEOGRAPHY. By C. B. CLARKE, M.A., F.G.S., F.R.S. New Edition, with Eighteen Coloured Maps. Fcap. 8vo. 3s.

A SHORT GEOGRAPHY OF THE BRITISH ISLANDS. By JOHN RICHARD GREEN and ALICE STOPFORD GREEN. With Maps. Fcap. 8vo. 3s. 6d.

A PRIMER OF GEOGRAPHY. By SIR GEORGE GROVE, D.C.L. With Illustrations. 18mo. 1s. [*Science Primers.*

ANCIENT GEOGRAPHY.

MANUAL OF ANCIENT GEOGRAPHY. Translated from the German of Dr. HEINRICH KIEPERT. Crown 8vo 5s.

HISTORY.

SHORT HISTORY OF THE ENGLISH PEOPLE. By JOHN RICHARD GREEN, M.A., LL.D., late Honorary Fellow of Jesus College, Oxford. With Coloured Maps, Genealogical Tables, and Chronological Annals. Crown 8vo. 8s. 6d. 122nd Thousand.

ANALYSIS OF ENGLISH HISTORY, based on Green's "Short History of the English People." By C. W. A. TAIT, M.A., Assistant Master, Clifton College. Crown 8vo. 3s. 6d.

GENERAL SKETCH OF EUROPEAN HISTORY. By EDWARD A. FREEMAN, D.C.L. New Edition, revised and enlarged, with Chronological Table, Maps, and Index. 18mo. 3s. 6d.

HISTORY OF ENGLAND. By EDITH THOMPSON. New Edition, revised and enlarged, with Coloured Maps. 18mo. 2s. 6d.

OUR NATIONAL INSTITUTIONS. A Short Sketch for Schools. By ANNA BUCKLAND. 18mo. 1s.

THE VICTORIAN HALF-CENTURY. By CHARLOTTE M. YONGE, Author of "The Heir of Redclyffe," "Cameos from English History," "A History of France," &c. With new Portrait of the Queen. Crown 8vo, paper covers, 1s.; cloth binding, 1s. 6d.

POLITICAL ECONOMY.

THE PRINCIPLES OF POLITICAL ECONOMY. By Professor HENRY SIDGWICK, M.A., LL.D., Knightbridge Professor of Moral Philosophy in the University of Cambridge, &c., Author of "The Methods of Ethics." 8vo. 16s.

POLITICAL ECONOMY—*continued.*

A MANUAL OF POLITICAL ECONOMY. By Right Hon. HENRY FAWCETT, F.R.S. Sixth Edition, revised, with a chapter on "State Socialism and the Nationalisation of the Land," and an Index. Crown 8vo 12s.

POLITICAL ECONOMY. By FRANCIS A. WALKER, M.A., Ph.D., Author of "Money," "Money in its Relation to Trade," &c. 8vo. 10s. 6d.

A BRIEF TEXT-BOOK OF POLITICAL ECONOMY. By FRANCIS A. WALKER, M.A., Ph.D., Author of "Money," "Money in its Relation to Trade," &c. Crown 8vo. 6s. 6d.

POLITICAL ECONOMY FOR BEGINNERS. By Mrs. FAWCETT. New Edition. With Questions, &c. Fcap. 8vo. 2s. 6d.

THE ECONOMICS OF INDUSTRY. By Professor A. MARSHALL and MARY P. MARSHALL. Fcap. 8vo. 2s. 6d.

PRIMER OF POLITICAL ECONOMY. By W. STANLEY JEVONS, LL.D., M.A., F.R.S. New Edition. 18mo. 1s. [*Science Primers.*

MENTAL AND MORAL PHILOSOPHY.

THE METHODS OF ETHICS. By Professor HENRY SIDGWICK, M.A., LL.D., &c. Third Edition. 8vo. 14s. A Supplement to the Second Edition, containing all the important Additions and Alterations in the Third Edition. Demy 8vo 6s.

THE HISTORY OF ETHICS, OUTLINES OF, FOR ENGLISH READERS. By HENRY SIDGWICK, M.A., LL.D., &c. Crown 8vo 3s. 6d.

THE ELEMENTS OF THE PSYCHOLOGY OF COGNITION. By the Rev. ROBERT JARDINE, B.D., D.Sc. (Edin.), Ex-Principal of the General Assembly's College, Calcutta Second Edition, revised and improved. Crown 8vo. 6s. 6d.

STUDIES IN DEDUCTIVE LOGIC. By the late W. STANLEY JEVONS, LL.D., M.A., F.R.S. Second Edition. Crown 8vo. 6s.

LESSONS IN LOGIC, INDUCTIVE AND DEDUCTIVE. By W. STANLEY JEVONS, LL.D., M.A., F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 3s. 6d.

A TEXT-BOOK OF DEDUCTIVE LOGIC FOR THE USE OF STUDENTS. By P. K. RAY, D.Sc. (Lond. and Edin.), Professor of Logic and Philosophy, Presidency College, Calcutta. Second Edition. Globe 8vo. 4s. 6d.

PRIMER OF LOGIC. By W. STANLEY JEVONS, LL.D., M.A., F.R.S. New Edition 18mo. 1s. [*Science Primers*

CRITIQUE OF PURE REASON. By IMMANUEL KANT. In commemoration of the Centenary of its first Publication. Translated into English by F. MAX MÜLLER. With an Historical Introduction by LUDWIG NOIRÉ. Two vols. Demy 8vo 16s. each.

Vol. I. HISTORICAL INTRODUCTION, by LUDWIG NOIRÉ; &c.

Vol. II. CRITIQUE of PURE REASON, translated by F. MAX MÜLLER.

For the convenience of students these volumes are now sold separately.

Of Prof. Max Müller's translation of the "Critique of Pure Reason," the *Times* says:—"Through this translation Kant's work has for the first time become international—the common property of the whole world."

AGRICULTURE.

AGRICULTURAL CHEMICAL ANALYSIS, A Handbook of. By PERCY FARADAY FRANKLAND, Ph.D., B.Sc., F.C.S., Associate of the Royal School of Mines, and Demonstrator of Practical and Agricultural Chemistry in the Normal School of Science and Royal School of Mines, South Kensington Museum. Founded upon *Leitfaden fur die Agricultur Chemische Analyse*, von Dr. F. KROCKER. Crown 8vo. 7s. 6d.

ELEMENTARY LESSONS IN THE SCIENCE OF AGRICULTURAL PRACTICE. By Professor H. TANNER. Fcap 8vo. 3s. 6d.

FIELD AND GARDEN CROPS, DISEASES OF. Chiefly such as are caused by Fungi. By WORTHINGTON G. SMITH, F.L.S. Fcap 8vo 4s 6d.

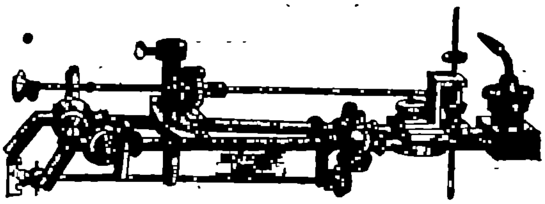
GOLD MEDAL,
International Inventions Exhibition, 1885.



NEW PATTERN OXY-HYDROGEN JET
FOR LIME-LIGHT LANTERN.

This jet, designed by LEWIS WRIGHT, Esq., gives a *most powerful light*, with a minimum of trouble. The lime-pin, of Bessemer steel, has a deep spiral cut in it, to which Newton's new check-action is fitted. By this arrangement, the whole lime-surface is used, yet the light never impinges twice on the same spot.

A new "cut-off," devised by ANDREW PRINGLE, Esq., is also fitted to these jets, by which the light can be turned up or down without altering the taps.

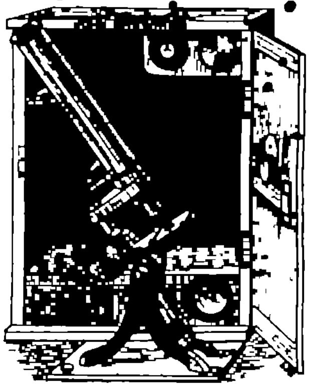
Can be seen at work at 3 Fleet Street.

Price, best workmanship, 47s. 6d. (as supplied to A. PRINGLE, Esq., who writes:—

"I write to let you know of the great success of the jet you made for me. It gives a grand light, and does not crack the limes as most jets do. Regarding the cut-off, every time I use it I like it better."

Price, without "cut-off" (as supplied to L. WRIGHT, Esq.), 32s. 6d.

NEWTON & CO., 3 Fleet Street, London, E.C.



BROWNING'S
"PERFECT"
MICROSCOPE.

The body is made entirely of brass and gun-metal, with rack-motion and fine screw adjustment. Three achromatic powers of excellent defining power, 1-inch, ½-inch, and ¼-inch; adjusting slide-holder to stage, revolving diaphragm, hand-forceps, stage-forceps, live-cage, &c. The whole packed in upright Mahogany Cabinet, with drawer for slides, dissecting-knives, &c.

PRICE £3 15s. 0d.

LECTURE ARRANGEMENTS AFTER EASTER 1887.

LECTURE HOUR, 3 o'clock p.m.

JOHN HOPKINSON, Esq., M.A., D.Sc., F.R.S., M.Inst.C.E., M.R.I.—Four Lectures on Electricity; on Tuesdays, April 19, 26, May 3, 10. Half-a-Guinea the Course.

VICTOR HORSLEY, Esq., F.R.S., B.S., F.R.C.S.—Three Lectures on the Modern Physiology of the Brain and its Relation to the Mind; on Tuesdays, May 17, 24, 31. Half-a-Guinea.

Prof. DEWAR, M.A., F.R.S., M.R.I., Fullerian Professor of Chemistry, R.I.—Seven Lectures on the Chemistry of the Organic World, on Thursdays, April 21, 28, May 5, 12, 19, 26, June 2. One Guinea.

R. VON LENDENFELD, Esq., Ph.D., F.L.L., B.Sc.—Three Lectures on Recent Scientific Researches in Australia; on Saturdays, April 23, 30, May 7. Half-a-Guinea.

JOHN W. HALES, Esq., M.A., Professor of English Literature at King's College, London.—Four Lectures on Victorian Literature. A General Survey of its Chronology, its Movements, and Tendencies—Some Leading Characteristics. On Saturdays, May 14, 21, 28, June 4. Half-a-Guinea.

The Rev. J. P. MAHAFFY, D.D., Professor of Ancient History in the University of Dublin.—Three Lectures on the Hellenism of Alexander's Empire. Lecture I. on Tuesday, June 7, Macedonia and Greece; Lecture II. on Thursday, June 9, Egypt; Lecture III. on Saturday, June 11, Syria. Half-a-Guinea.

Subscription (to Non-Members) to all the Courses during the Season, Two Guineas. Tickets issued daily.

Members may purchase *not less than Three Single Lecture Tickets*, available for any Lecture for Half-a-Guinea.

The FRIDAY EVENING MEETINGS will be resumed on April 22, at 8 p.m., when Sir FREDERICK ABEL, C.B., will give a Discourse on The Work of the Imperial Institute, at 9 p.m. Succeeding Discourses will probably be given by Prof. HELE SHAW, Dr. T. LAUDER BRUNTON, Dr. J. S. BURDON SANDERSON, Mr. BENJAMIN BAKER, Dr. EDWARD E. KLEIN, Dr. DAVID GILL, and other gentlemen. To these Meetings Members and their Friends only are admitted.

Persons desirous of becoming Members are requested to apply to the SECRETARY. When proposed they are immediately admitted to all the Lectures, to the Friday Evening Meetings, and to the Library and Reading-Rooms; and their Families are admitted to the Lectures at a reduced charge. Payment: First Year, Ten Guineas; afterwards, Five Guineas a Year; or a composition of Sixty Guineas.

PRELIMINARY SCIENTIFIC EXAMINATION.

UNIVERSITY OF LONDON.

A Special Course of Lectures and Practical Work (four afternoons a week) "On Biology (Animal Portion)," under the Direction of Prof. RAY LANKESTER, will be given at University College, London, during the Summer Session, adapted to the requirements of Candidates for the above Examination. To commence MAY 5.

A Course of Lectures will also be given by Dr. R. VON LENDENFELD, Assistant in the Zoological Laboratory of University College, on "Parasitic Worms," commencing on the same day, and adapted to the requirements of Students of Medicine and Zoology.

For further particulars, apply to the SECRETARY, University College, London.

Prof. HENRICI, F.R.S., will Deliver a

Course of Eight Lectures "On the Method of Least Squares, with Applications to Physical and Chemical Problems," on Mondays from 5 to 6 p.m., commencing on MONDAY, MAY 2, at the Central Institution of the City and Guilds of London Institute. A Previous Knowledge of the Differential Calculus will not be necessary. Fee for the Course, Ten Shillings. For Syllabus, apply at Central Institution, Exhibition Road, S.W.

PHILIP MAGNUS, Director and Secretary.

CITY AND GUILDS OF LONDON INSTITUTE.

TECHNOLOGICAL EXAMINATIONS, 1887.

EXAMINATIONS in TECHNOLOGY will take place at the different Centres throughout the Kingdom on WEDNESDAY Evening, May 25, 1887, at 7 o'clock, and on SATURDAY, May 21, from 5 to 7 p.m.

The latest date for sending in Returns of Candidates who wish to be examined in May next is TUESDAY, April 19, after which date no application can be received. Secretaries are requested to inform all Teachers, Students, and intending Candidates at their respective Centres, that the Examinations in the branches of Textiles, in Weaving and Pattern Designing, and in Practical Typography and Practical Plumbing, will be held on May 21, and not on May 28, as previously announced.

Individual Candidates who are unable to arrange to be examined at a Provincial or any other Centre can, on application to the Director and Secretary, be examined in London at the Central Institution, Exhibition Road, S.W.

The Examinations will be held in 50 Subjects.

A programme, containing syllabus of each subject and last year's examination questions, can be obtained from the Offices, Exhibition Road, S.W., or Gresham College, E.C.

PHILIP MAGNUS, Director and Secretary.

GEOLOGICAL FIELD-CLASS.—Summer

1887.—For Studying the Country near London. Directed by Prof. H. G. SEELEY, F.R.S., King's College. Commencing at end of this month.—For further particulars, apply to W. W. R. MAY, 26 Bethune Road, Manor Road, Stoke Newington, N.

LIVING SPECIMENS FOR THE MICROSCOPE.

GOLD MEDAL awarded at the FISHERIES EXHIBITION to

THOMAS BOLTON, 57 NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers Spirogyra in conjugation, with drawing and description. He also sent out Freshwater Mussel Spat, Salmon Fry, Lophopus crystallinus, Philodina roseola, Melicerta ringens, Stephanoceros Eichhornii, Ephemera Larva, Volvox globator; also Hydra, Amoeba, Vorticella, Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s., or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

"BROWN CEMENT."

The name of this Cement, admitted to be the best for Microscopical Work, has been registered, and is now labelled in White Letters upon a Brown Ground.

Purchasers should see that they are not deceived by fraudulent imitations.

Price 1s. per bottle, with full instructions for use, from most Opticians. Post free for 1s. 3d. from

EDWARD WARD, 249 Oxford Street, Manchester. [503

CURRICULUM OF THE M.D. DEGREE,

LONDON.

Students who have Matriculated and are intending to enter or who have already entered at any one of the London Medical Schools for the purely Medical Portion of their Studies, can prepare for the PRELIMINARY SCIENTIFIC EXAMINATION at University College, under Prof. Williamson, LL.D., F.R.S., Prof. Carey Foster, F.R.S., Prof. Oliver, F.R.S., and Prof. Lankester, LL.D., F.R.S.

Fee for the complete Course of Study required, including Lectures and Laboratory Work, 35 Guineas.

For particulars apply to the SECRETARY, University College, Gower Street.

UNIVERSITY COLLEGE, LONDON.

ADVANCED INORGANIC CHEMISTRY.

DR. S. RIDEAL will give a Course of Thirty Lectures on Mondays, Wednesdays, and Fridays, at 4 p.m., commencing APRIL 20. The Course is fitted for Students reading for Honours in Chemistry at the University of London July Examinations. Recent Progress in Physical Chemistry and the Study of the Rarer Elements form part of the Course. Fee, £2 2s.

J. M. HORSBURGH, M.A., Secretary.

LIVERPOOL SCHOOL BOARD.

The Liverpool School Board will shortly require an ASSISTANT SCIENCE DEMONSTRATOR in connexion with the Instruction in Mechanics and Domestic Economy (New Code, Fourth Schedule) given in their Schools.

One with some experience in teaching large Classes in Elementary Schools and some practical knowledge of Elementary Physics and Chemistry, will be preferred.

Salary, £100 the first year, rising in four years to £150, with an extra annual payment of from £3 to £11 if applicant holds Science and Art Certificates and University distinctions.

Applications, stating age, qualifications, and experience, and including Copies of Testimonials, to be sent not later than April 26, addressed to

EDWARD M. HANCE, Clerk to the Board.

Municipal Offices, April 7, 1887.

LONDON HOSPITAL AND MEDICAL COLLEGE,

MILE-END, E.

The SUMMER SESSION will commence on MONDAY, May 2.

The New College Buildings are now complete, and afford more than double the former accommodation.

Intending Students are advised that under the new regulations of the Examining Board in England, it is exceedingly advantageous to enter for the Summer Session. Students now entering are also eligible for the Entrance Scholarships in September.

The Hospital contains nearly 800 beds, and is the largest General Hospital in Great Britain.

General Fee for Lectures and Hospital Practice, 90 guineas in one sum, or 100 guineas in three instalments. The Resident and other Hospital Appointments are free to full Students.

Special entries may be made for Medical and Surgical Practice, also for the course of Practical Surgery.

The London Hospital is now in direct communication by rail and tram with all parts of the Metropolis, and the Metropolitan, Metropolitan District, South-Eastern, and East London Railways have stations within a minute's walk of the Hospital and College.

For Prospectus and particulars apply to

MUNRO SCOTT, Warden.

Sale by Auction.

SALE OF A NATURAL HISTORY COLLECTION IN COPENHAGEN.

ON WEDNESDAY, APRIL 20, 1887, at 10 a.m. and 5 p.m., and following Days, will be Sold the Natural History Collections of the late R. CONRADSON, Conservator, consisting of MAMMALS, BIRDS, REPTILES, and FISHES, partly mounted, partly in the skin, and partly in spirits. Also, Articulata and Mollusks in spirits, and Collections of Eggs, &c. In these Collections the following are specially to be noted:—Rare Skins of Mammals and Birds from New Holland, Samoa Islands, Java, &c., and a valuable Collection of Works on Natural History.

All the above will be Sold by Auction at the Hotel Phönix, Dronningens Tværgade, N 1¹.

The Books will be sold at 5 p.m. on April 20.

The above Collections will be on view on April 18 and 19, from 11 a.m. to 5 p.m., at Bredgade No. 35.

Catalogues may be had from Advocat KLUBIEN, Bredgade No. 43, to whom payment is to be made.

Messrs. LYNGE, of Walkendorffsgade 8, and KLEIN, of Pilestræde 40, Booksellers, will receive Commissions.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

HYDE PARK CORNER, S.W.

The SUMMER SESSION will commence on MONDAY, May 2.

The Fees for Perpetual Students are £125 on entrance, or £130 paid by instalments extending over three years.

£10 10s will be deducted from these Fees in the case of Students who, under the conjoint scheme, do not require instruction in Chemistry and Materia Medica.

Second- and third-year Students are received upon payment of £90 and £65 respectively.

Dresserships, Clerkships, and all the House Appointments are awarded without extra Fees, and the latter on result of competition.

The William Brown £100 Exhibition, tenable for two years, and the £40 Exhibition, tenable for three years, are open to all Perpetual Students.

The following Entrance Scholarships are offered for competition in OCTOBER, and Students entering in the Summer Session are eligible to compete for them.

(1) A Scholarship, value £125, *for the Sons of Medical Men* who have entered the School during the current year.

(2) Two Scholarships, value £50 each, open to all Students commencing their Studies in May or October. *Subjects, Latin, French, or German, and Elementary Physics.*

(3) A Scholarship, value £90, open to all Students who have entered the School during the current year, having passed the Cambridge 1st M.B. since the previous October. *Subjects, Practical Chemistry and Elementary Biology, Physiology, and Anatomy.*

(4) A Scholarship, value £65, open to all Students who have entered the School during the current year having been previously signed up for, or passed the Oxford 1st M.B. or Cambridge 2nd M.B. *Subjects, Anatomy and Physiology.*

Other Prizes of the value of £150 are offered for competition Annually.

The Appointments of Obstetric Assistant, with a Salary of £100 a Year and Board and Lodging; Curator, £50; Medical and Surgical Registrars, £50 each, are awarded yearly upon the recommendation of the Medical School Committee.

The New Physiological Laboratories are now finished, and have been placed under the superintendence of Dr Delépine.

Prospectuses and fuller details may be obtained by application to

WILLIAM WADHAM, M.D., Dean.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, S.E.

The SUMMER SESSION will commence on May 2. Students entering in the summer are eligible to compete for the Science Scholarships of 125 Guineas and £60, awarded in October.

There are numerous Prizes and Scholarships, and all Appointments are open to Students without extra charge.

Special Classes for the Examinations of the University of London are held throughout the year. A Register of Approved Lodgings and of Private Families receiving Students to reside is kept in the Secretary's Office.

Prospectus and all particulars can be obtained from the Medical Secretary, Mr. G. RENDLE.

W. M. ORD, Dean.

ROCKS, MINERALS, FOSSILS.

F. H. BUTLER,

Assoc. R. S. Mines Lond., M.A. Oxon., L.S.A. Lond., &c.,

Successor to the late R. TALLING,

180 BROMPTON ROAD, LONDON, S.W.

A limited number of the recently described Cornish CRYSTALLISED DUFRENITE, new to Great Britain, in stock; also a fresh series of foreign and Scotch rocks and rock-sections. The Pelecypoda and Echinodermata of the Wright Collection, now fully arranged, on view.

EAST GRINSTEAD COLLEGIATE SCHOOL,

MAYPOLE ROAD, SUSSEX.

The object of the School is to afford a Sound Education, which will fit boys for either Professional or Commercial life. Most careful attention is paid to the requirements of boys intended for commercial pursuits. Boys are received from seven to fourteen years of age. There is a Junior Class, specially adapted to prepare the younger boys for the work of the higher classes. Each pupil will receive careful attention, especially in those subjects wherein he is weak. No injurious cramming encouraged. The course of Instruction includes all the subjects required at the various public examinations. The Principal has had many years' experience in good schools, and has proved himself a most successful Master. The Fees are moderate.—For Prospectus and particulars, apply to the PRINCIPAL.

AGRICULTURAL COLLEGIATE SCHOOL,

EAST GRINSTEAD, SUSSEX.

For Sons of Gentlemen, from seven years of age. The Course of Studies or Instruction is designed to prepare boys to occupy the positions of Landowners, Land Agents, Farmers, intending Colonists, &c. It provides full instruction in the practice and science of Agriculture and Estate Management, Management of Live Stock, Dairy Farming, Agricultural Chemistry, &c. Pupils are prepared for all the Examinations.

The College offers the following advantages:—A most superior education. A Staff of Masters selected for their qualifications as Scholars and their tried ability as Teachers. A Boarding Department carefully supervised and excellently appointed; its diet liberal, and all arrangements calculated to develop gentlemanly habits, and to produce feelings of self-respect.

The strictest attention to the moral and religious training of Pupils. Fees most moderate. References of high character to Parents of Pupils.

Prospectus and all particulars on application to the PRINCIPAL.

MINERALOGY AND GEOLOGY.

CHOICE SPECIMENS FOR MUSEUMS AND PRIVATE COLLECTORS: BERYLS, TOPAZES, RUTILES ON MATRIX, CELESTINE, OPALS, &c., &c.

RARE MINERALS FOR SCIENTIFIC RESEARCH; COLLECTIONS FOR STUDENTS AND PROSPECTORS.

VERY FINE POLISHED SECTIONS OF AMMONITES AND NAUTILI.

NEW SERIES OF ROCKS. MICROSCOPIC SLIDES.

Hammers, Chisels, and Blow-pipe Apparatus.

PRIVATE LESSONS AND EVENING CLASSES.

CATALOGUES ON APPLICATION.

SAMUEL HENSON,

277 STRAND, LONDON,

Opposite Norfolk Street.

NATURALISTS' GLASS-CAPPED BOXES.

Museums and Private Collectors supplied with Round and Rectangular Glass-capped Boxes from One Shilling per dozen. About 70 different sizes always in Stock. A cheap Glazed Box, 14 inches by 10 inches, for One Shilling. Samples Post Free, Two Shillings.

THOMAS D. RUSSELL,

PRIZE MEDALLIST, HEALTH EXHIBITION,

78 NEWGATE STREET, LONDON, E.C.

SIX PRIZE MEDALS

AWARDED FOR GEOLOGICAL COLLECTIONS.

Geological Collection especially adapted for Teaching as supplied to Science and Art Department, and used by all Lecturers and Teachers in Great Britain, &c.

New and Rare Minerals constantly arriving from all parts for selection of Single Specimens.

ROCK SECTIONS AND ROCK SPECIMENS:

The Largest Variety in England.

New Catalogues and Lists on application to—

JAMES R. GREGORY,

88 CHARLOTTE STREET, FITZROY SQUARE, LONDON.

Established 27 Years in London.

BOOKS (Secondhand), Miscellaneous, Remainders, &c.—C. HERBERT, English and Foreign Bookseller, 319 Goswell Road, London, E.C. Catalogue free on receipt of two stamps. Libraries, Old Books, and Parchments purchased.

THE MASON SCIENCE COLLEGE, BIRMINGHAM.

PROFESSORSHIP OF PHYSIOLOGY.

The Council invite Applications, on or before June 30 next, for the above Appointment, the duties of which will commence on October 1, 1887.

Particulars of the Stipend and Conditions will be sent on application to the undersigned, to whom all Applications for the Appointment should be sent.

By a Resolution of the Council, Candidates are especially requested to abstain from canvassing.

GEO. H. MORLEY, Secretary.

PRELIMINARY SCIENTIFIC EXAMINATION.

UNIVERSITY OF LONDON.

A Special Course of Lectures and Practical Work (four afternoons a week) "On Biology (Animal Portion)," under the Direction of Prof RAY LANKESTER, will be given at University College, London, during the Summer Session, adapted to the requirements of Candidates for the above Examination. To commence MAY 5

A Course of Lectures will also be given by Dr. R VON LENDENFELD, Assistant in the Zoological Laboratory of University College, on "Parasitic Worms," commencing on the same day, and adapted to the requirements of Students of Medicine and Zoology.

For further particulars, apply to the SECRETARY, University College, London

---

Prof. HENRICI, F.R.S., will Deliver a

Course of Eight Lectures "On the Method of Least Squares, with Applications to Physical and Chemical Problems," on Mondays from 5 to 6 p.m., commencing on MONDAY, MAY 2, at the Central Institution of the City and Guilds of London Institute. A Previous Knowledge of the Differential Calculus will not be necessary. Fee for the Course, Ten Shillings. For Syllabus, apply at Central Institution, Exhibition Road, S.W.

PHILIP MAGNUS, Director and Secretary

LIVERPOOL SCHOOL BOARD.

The Liverpool School Board will shortly require an ASSISTANT SCIENCE DEMONSTRATOR in connection with the Instruction in Mechanics and Domestic Economy (New Code, Fourth Schedule) given in their Schools.

One with some experience in teaching large Classes in Elementary Schools and some practical knowledge of Elementary Physics and Chemistry, will be preferred.

Salary, £100 the first year, rising in four years to £150, with an extra annual payment of from £3 to £11 if applicant holds Science and Art Certificates and University distinctions.

Applications, stating age, qualifications, and experience, and inclosing Copies of Testimonials, to be sent not later than April 26, addressed to

EDWARD M. HANCE, Clerk to the Board.

Municipal Offices, April 7, 1887.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, S.E.

The SUMMER SESSION will commence on May 2. Students entering in the summer are eligible to compete for the Science Scholarships of 125 Guineas and £60, awarded in October

There are numerous Prizes and Scholarships, and all Appointments are open to Students without extra charge

Special Classes for the Examinations of the University of London are held throughout the year. A Register of Approved Lodgings and of Private Families receiving Students to reside is kept in the Secretary's Office.

Prospectus and all particulars can be obtained from the Medical Secretary, Mr. G. RENDLE.

W. M ORD, Dean.

LONDON HOSPITAL AND MEDICAL COLLEGE.

MILE-END, E.

The SUMMER SESSION will commence on MONDAY, May 2.

The New College Buildings are now complete, and afford more than double the former accommodation.

Intending Students are advised that, under the new regulations of the Examining Board in England, it is exceedingly advantageous to enter for the Summer Session Students now entering are also eligible for the Entrance Scholarships in September.

The Hospital contains nearly 800 beds, and is the largest General Hospital in Great Britain

General Fee for Lectures and Hospital Practice, 90 guineas in one sum, or 100 guineas in three instalments The Resident and other Hospital Appointments are free to full Students.

Special entries may be made for Medical and Surgical Practice, also for the course of Practical Surgery.

The London Hospital is now in direct communication by rail and tram with all parts of the Metropolis, and the Metropolitan, Metropolitan District, South-Eastern, and East London Railways have stations within a minute's walk of the Hospital and College

For Prospectus and particulars apply to

MUNRO SCOTT, Warden.

LIVING SPECIMENS FOR THE MICROSCOPE.

THOMAS BOLTON, 57 NEWHALL STREET, BIRMINGHAM,

Who last week sent to his Subscribers Melicerta conifera, with description. He also sent out Floscularia ornata, Stephanoceros Eichhornii, Cordylophora lacustris, Salmon Fry, Frog Tadpoles, Lophopus crystallinus, Glass Larva, Ephemera Larva, Volvox globator; also Hydra, Amoeba, Vorticella Crayfish, and other Specimens for (Huxley and Martin's) Biological Laboratory work.

Weekly Announcements will be made in this place of Organisms T. B. is supplying.

Specimen Tube, One Shilling, post free.

Twenty-six Tubes in Course of Six Months for Subscription of £1 1s. or Twelve Tubes for 10s. 6d.

Portfolio of Drawings, Eleven Parts, 1s. each.

GUY'S HOSPITAL MEDICAL SCHOOL.

The SUMMER SESSION commences on MONDAY, May 2.

The Hospital contains, besides the beds for Medical and Surgical Cases, wards for Obstetric, Ophthalmic, and other special departments.

Special Classes are held in the Hospital for Students preparing for the Examinations of the University of London and other Examining Boards.

APPOINTMENTS.—The House Surgeons and House Physicians, the Obstetric Residents, Clinical Assistants, and Dressers, are selected from the Students according to merit and without payment There are also a large number of Junior Appointments, every part of the Hospital Practice being systematically employed for instruction.

ENTRANCE SCHOLARSHIPS.—Open Scholarship of 125 guineas, in Classics Mathematics, and Modern Languages Open Scholarship of 125 guineas, in Chemistry, Physics, Botany, and Zoology

Students entering in May are eligible for the Open Scholarships competed for in September.

Seventeen Scholarships, Prizes, and Medals varying from £50 to £10 each are open for competition to all the Students

The Hospital is in close proximity to the Metropolitan, District, South-Eastern, Brighton, Chatham, North London, and Great Eastern Railway systems.

For Prospectus apply to the Dean, Dr F. TAYLOR, Guy's Hospital, London, S.E.

March 1887.

GUY'S HOSPITAL MEDICAL SCHOOL.

UNIVERSITY OF LONDON, PRELIMINARY SCIENTIFIC (M.B.) EXAMINATION.

Instruction is given in all the subjects of the above Examination at GUY'S HOSPITAL during the Winter and Summer Sessions. The Fee for the whole Course is 10 Guineas. The Class is not confined to Students of the Hospital

For further particulars, apply to the DEAN, Guy's Hospital, Southwark, S.E.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

HYDE PARK CORNER, S.W.

The SUMMER SESSION will commence on MONDAY, May 2

The Fees for Perpetual Students are £125 on entrance, or £130 paid by instalments extending over three years.

£10 10s. will be deducted from these Fees in the case of Students who, under the conjoint scheme, do not require instruction in Chemistry and Materia Medica

Second- and third-year Students are received upon payment of £90 and £65 respectively.

Dresserships, Clerkships, and all the House Appointments are awarded without extra Fees, and the latter on result of competition.

The William Brown £100 Exhibition, tenable for two years, and the £40 Exhibition, tenable for three years, are open to all Perpetual Students.

The following Entrance Scholarships are offered for competition in OCTOBER, and Students entering in the Summer Session are eligible to compete for them.

(1) A Scholarship, value £125, *for the Sons of Medical Men* who have entered the School during the current year.

(2) Two Scholarships, value £50 each, open to all Students commencing their Studies in May or October. *Subjects, Latin, French, or German, and Elementary Physics*

(3) A Scholarship, value £60, open to all Students who have entered the School during the current year, having passed the Cambridge 1st M.B. since the previous October *Subjects, Practical Chemistry and Elementary Biology, Physiology, and Anatomy.*

(4) A Scholarship, value £65, open to all Students who have entered the School during the current year having been previously signed up for, or passed the Oxford 1st M.B. or Cambridge 2nd M B. *Subjects, Anatomy and Physiology.*

Other Prizes of the value of £150 are offered for competition Annually.

The Appointments of Obstetric Assistant, with a Salary of £100 a Year and Board and Lodging; Curator, £50; Medical and Surgical Registrars, £50 each, are awarded yearly upon the recommendation of the Medical School Committee.

The New Physiological Laboratories are now finished, and have been placed under the superintendence of Dr [illegible].

Prospectuses and fuller details may be obtained by application to

WILLIAM WADHAM, M.D., Dean.

Sale by Auction.

Monday Next, Sale No. 7403.

NATURAL HISTORY SPECIMENS.

MR. J. C. STEVENS will Sell by Auction at his Great Rooms, 38 King Street, Covent Garden, on MONDAY NEXT, April 25, at half-past 12 precisely, a Collection of Minerals and Fossils, including many beautiful cut and polished Specimens, a portion of the Collection of Birds' Eggs formed by Capt. BARTON, of Bideford; British and Exotic Lepidoptera, Bird and Animal Skins, and other Natural History Specimens, Curiosities, Cabinets, &c.

On view the Saturday prior from 10 till 4, and Morning of Sale, and Catalogues had.

EAST GRINSTEAD COLLEGIATE SCHOOL,

MAYPOLE ROAD, SUSSEX.

The object of the School is to afford a Sound Education, which will fit boys for either Professional or Commercial life. Most careful attention is paid to the requirements of boys intended for commercial pursuits. Boys are received from seven to fourteen years of age. There is a Junior Class, specially adapted to prepare the younger boys for the work of the higher classes. Each pupil will receive careful attention, especially in those subjects wherein he is weak. No injurious cramming encouraged. The course of Instruction includes all the subjects required at the various public examinations. The Principal has had many years' experience in good schools, and has proved himself a most successful Master. The Fees are moderate.—For Prospectus and particulars, apply to the PRINCIPAL.

AGRICULTURAL COLLEGIATE SCHOOL,

EAST GRINSTEAD, SUSSEX.

For Sons of Gentlemen, from seven years of age. The Course of Studies or Instruction is designed to prepare boys to occupy the positions of Landowners, Land Agents, Farmers, intending Colonists, &c. It provides full instruction in the practice and science of Agriculture and Estate Management, Management of Live Stock, Dairy Farming, Agricultural Chemistry, &c. Pupils are prepared for all the Examinations.

The College offers the following advantages:—A most superior education. A Staff of Masters selected for their qualifications as Scholars and their tried ability as Teachers. A Boarding Department carefully supervised and excellently appointed; its diet liberal, and all arrangements calculated to develop gentlemanly habits, and to produce feelings of self-respect.

The strictest attention to the moral and religious training of Pupils. Fees most moderate. References of high character to Parents of Pupils.

Prospectus and all particulars on application to the PRINCIPAL.

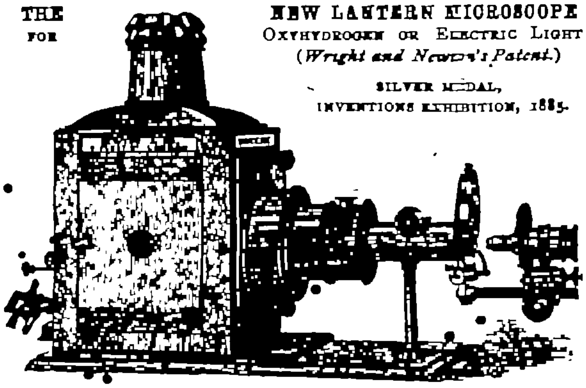
FOR OXYHYDROGEN OR ELECTRIC LIGHT
(*Wright and Newton's Patent.*)

SILVER MEDAL,
INVENTIONS EXHIBITION, 1885.



With Lime-light this Instrument shows a Flea 15 feet long as sharply as a Magic Lantern Slide, Proboscis of Blow-fly 1½ feet long, Cornea of Fly's Eye magnified 2,500 diams. Is also the most perfect projecting Micro-Polariscope made. Particulars and Report of Royal Microscopical Society on application.

NEWTON & CO.,
OPTICIANS TO THE QUEEN AND THE GOVERNMENT
MAKERS OF EVERY DESCRIPTION OF SCIENTIFIC AND PHYSICAL APPARATUS FOR COLLEGES, INSTITUTIONS, &c. SPECIAL OPTICAL APPARATUS FOR POLARISCOPY, SPECTROSCOPY, &c., FOR SCREEN PROJECTION.
Full Illustrated Catalogues 6 Stamps.
3 FLEET STREET, LONDON.

MINERALS AND STONE IMPLEMENTS.

MR. BRYCE-WRIGHT begs to call the attention of his Clients and the Public to his large Series of

MINERALS AND STONE IMPLEMENTS

from which single specimens can be selected.
Elementary Collections of Minerals, Fossils, and Rocks from £1 upwards.
N.B.—These Collections obtained the Prize Medal, 1862.

GEMS AND PRECIOUS STONES OF EVERY DESCRIPTION.

BRYCE-WRIGHT,
Mineralogist and Expert in Precious Stones,
204 REGENT STREET, LONDON, W.

This Day is Published, 8vo, Sewed, 6d.

A LIST OF BRITISH BIRDS. Revised to April 1887 by HOWARD SAUNDERS, F.L.S., &c., Editor of Vols. III. and IV. of the Fourth Edition of Yarrell's "History of British Birds"

For Labelling Specimens, or for Reference; the various Species, whether those breeding in the British Islands, occasional visitors, or of doubtful history, being distinctively printed.

GURNEY & JACKSON (Successors to MR. VAN VOORST),
1, Paternoster Row.

HARMONIES OF TONES AND COLOURS,
DEVELOPED BY EVOLUTION.
By F. J. HUGHES.

With Supplement. Illustrated with Coloured Diagrams.
Imperial 8vo, Cloth, price 21s.

The Supplement can be had in Paper Covers, price 2s. 6d.

MARCUS WARD & CO., LTD., London, Belfast, and New York.

Just Published, Demy 8vo, price 18s.

THE GEOLOGY OF ENGLAND AND WALES. By HORACE B. WOODWARD, F.G.S., of the Geological Survey of England. Second Edition, thoroughly Revised and much Enlarged, with entirely new Geological Map (size 22 × 27 inches) and numerous Illustrations.

GEORGE PHILIP & SON, 32 Fleet Street, London,
Liverpool: Caxton Buildings.

Crown 8vo, 8s. 6d.

Catalogue per post 8d.

LEWIS WRIGHT'S

PROJECTION POLARISCOPE

Showing axes of Crystals, &c., on a well illuminated and flat field.

NEW FORM OF HELIOSTAT

With specially strong and steady Clock-movement, 4 inches aperture.

Price from £10 10s. 0d. to £20.

SPECTROSCOPES

FOR THE OBSERVATORY OR LABORATORY,
FOR SOLAR, STELLAR, METEOR, RAINBAND, OR CHEMICAL RESEARCHES.

Of every Size and Description.

With prisms, either ordinary, simple and compound, with automatic adjustment to minimum deviation, or direct vision; or with gratings, flat or concave. All of the highest efficiency and workmanship.

ADAM HILGER,

Astronomical and Optical Instrument Maker,

204 STANHOPE STREET, HAMPSTEAD ROAD, N.W.

ROCKS, MINERALS, FOSSILS.

F. H. BUTLER,

Assoc. R. S. Mines Lond., M.A. Oxon., L.S.A. Lond., &c.,

Successor to the late R. TALLING,

180 BROMPTON ROAD, LONDON, S.W.

On View:—A fine series of British and Continental Cretaceous and Jurassic Cephalopoda, including many Ammonites of great rarity; Ammonites from the Hallstadt Trias; and Ceratites and Encrinites from the Muschelkalk; also a selection of Archaic and Transition Greek Pottery from Rhodes, Romano-Punic from Utica, and Romano-British and Celtic from London and New Forest and Ireland.

HOLLOWAY'S PILLS

THIS MEDICINE

Is a Certain Cure for all Disorders of the LIVER, STOMACH AND BOWELS. A Great PURIFIER of the BLOOD; a Powerful Invigorator of the System, in cases of WEAKNESS AND DEBILITY, and is unequalled in Female Complaints.

THE ZOOLOGIST:

A MONTHLY MAGAZINE OF NATURAL HISTORY.

Third Series. Edited by J. E. HARTING, F.L.S., F.Z.S., Member of the British Ornithologists' Union; contains—

Original Articles by well-known naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds; occurrence of rare birds; distribution and migration of British fresh-water fish; new or rare marine fish; local aquaria; British reptiles; British land and fresh-water mollusca, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

DER NATURFORSCHER,

Wochenblatt zur Verbreitung der Fortschritte in den Naturwissenschaften, XIX. Jahrgang.

Gegründet von Dr. W. SKLAREK, u. herausgegeben von Dr. O. SCHUMANN, Privatdocent an der Universität Tübingen.

Price for 52 Numbers, 16s. per annum, or 18s. 6d. post free.

Tübingen: LAUPP.

London and Edinburgh: WILLIAMS & NORGATE.

On the 1st of every Month, price Sixpence.

THE ENTOMOLOGIST:

AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOGY.

Edited by JOHN T. CARRINGTON

With the Assistance of

FREDERICK BOND, F.Z.S. | RICHARD SOUTH.
EDWARD A. FITCH, F.L.S. | J. JENNER WEIR, F.L.S.
F. BUCHANAN WHITE, M.D.

Contains Articles by well-known Entomologists on all Branches of the Science; on Insects injurious or beneficial to Farm or Garden; Notes on Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthly Lists of Duplicates and Desiderata.

WOODCUT ILLUSTRATIONS and occasional LITHOGRAPHED and CHROMO-LITHOGRAPHED PLATES.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

THE "HANSA,"

Published since 1864 in Hamburg, is the only independent professional paper in Germany dedicated exclusively to Maritime Objects. Essays, Critiques, Reviews, Reports, Advertisements. Strict eye kept upon the development of Maritime Affairs in every respect. Every second Sunday one Number in 4to at least; frequent supplements and drawings. Subscription at any time; preceding numbers of the year furnished subsequently. Price 12s. for twelve months. Advertisements 4d. a line widely spread by this paper; considerable abatement for 3, 6, 12 months' insertion. Business Office: Aug. Meyer and Dieckmann, Hamburg, Alterwall, 28. Edited by W. von FREEDEN M.R. Hamburg, Alexander Street, 8.

THE ENTOMOLOGIST'S MONTHLY MAGAZINE.

Price Sixpence, Monthly, 24 pages 8vo, with occasional Illustrations.

Conducted by C. G. BARRETT, J. W. DOUGLAS, W. W. FOWLER, M.A., F.L.S., R. MCLACHLAN, F.R.S., E. SAUNDERS, F.L.S., and H. T. STAINTON, F.R.S.

This Magazine, commenced in 1864, contains standard articles and notes on all subjects connected with Entomology, and especially on the Insects of the British Isles.

Subscription—Six Shillings per Volume, post free. The volumes commence with the June number in each year.

Vols. I. to VI. (strongly bound in cloth) may be obtained by purchasers of the entire set to date, at the increased price of 10s. each; the succeeding vols. may be had separately or together, at 7s. each.

London: GURNEY & JACKSON (Mr. Van Voorst's successors),
1 Paternoster Row.

N.B.—Communications, &c., should be sent to the Editors at the above address.

NORTH BRITISH AGRICULTURIST,

the chief Agricultural Journal in Scotland, circulates extensively among Landowners, Farmers, Resident Agents, and others interested in the management of land throughout the United Kingdom.

The AGRICULTURIST is published every Wednesday afternoon in time for the Evening Mails, and contains Reports of all the principal British and Irish Markets of the week.

The special attention of Land Agents is directed to the AGRICULTURIST as one of the best existing papers for Advertising Farms to be Let and Estates for Sale.

Advertisers addressing themselves to Farmers will find the AGRICULTURIST a first-class medium for reaching this Class.

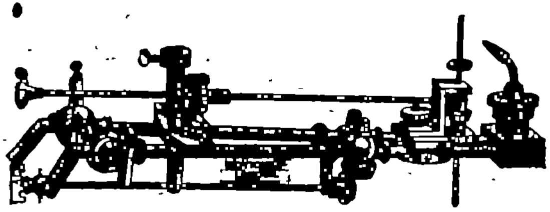
NEW PATTERN OXY-HYDROGEN JET
FOR LIME-LIGHT LANTERN.



This jet, designed by LEWIS WRIGHT, Esq., gives a *most powerful light*, with a minimum of trouble. The lime-pin, of Bessemer steel, has a deep spiral cut in it, to which Newton's new check-action is fitted. By this arrangement, the whole lime-surface is used, yet the light never impinges twice on the same spot.

A new "cut-off," devised by ANDREW PRINGLE, Esq., is also fitted to these jets, by which the light can be turned up or down without altering the taps.

Can be seen at work at 3 Fleet Street.

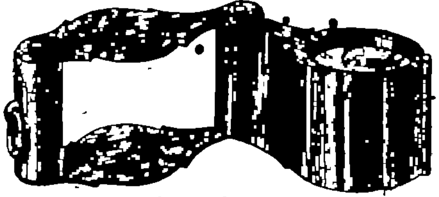
Price, best workmanship, 47s. 6d., as supplied to A. PRINGLE, Esq., who writes:—

"I write to let you know of the great success of the jet you made for me; it gives a grand light, and does not crack the lime as most jets do. Regarding the cut-off, every time I use it I like it better."

Price, without "cut-off" (as supplied to L. WRIGHT, Esq.), 32s. 6d.

NEWTON & CO., 3 Fleet Street, London, E.C.

BROWNING'S PLATYSCOPIC LENS.



Engraved Real Size.

A NEW ACHROMATIC COMBINATION,
COMBINING THE DEFINITION OF A MICROSCOPE WITH THE PORTABILITY OF A POCKET LENS.

"If you carry a small Platyscopic Pocket Lens (which every observer of Nature ought to do)."—GRANT ALLEN in *Knowledge*.

The Platyscopic Lens is invaluable to botanists, mineralogists, or entomologists, as it focuses about three times as far from the object as the Coddington Lenses. This allows opaque objects to be examined easily.

The Platyscopic Lens is made of four degrees of power, magnifying respectively 10, 15, 20, and 30 diams.; the lowest power, having the largest field, is the best adapted for general use.

The Lenses are set in Ebonite Cells, and mounted in Tortoiseshell Frames.

Price of the Platyscopic Lens, mounted in Tortoiseshell, magnifying either 10, 15, 20, *or* 30 *diameters*, 18*s*. 6*d*. *each power*.

Illustrated description sent free.

CURRICULUM OF THE M.D. DEGREE, LONDON.

Students who have Matriculated and are intending to enter or who have already entered at any one of the London Medical Schools for the purely Medical Portion of their Studies, can prepare for the PRELIMINARY SCIENTIFIC EXAMINATION at University College, under Prof. Williamson, LL.D., F.R.S., Prof. Carey Foster, F.R.S., Prof. Oliver, F.R.S., and Prof. Lankester, LL.D., F.R.S.

Fee for the complete Course of Study required, including Lectures and Laboratory Work, 35 Guineas.

For particulars apply to the SECRETARY, University College, Gower Street.

Prof. HENRICI, F.R.S., will Deliver a

Course of Eight Lectures "On the Method of Least Squares, with Applications to Physical and Chemical Problems," on Mondays from 5 to 6 p.m., commencing on MONDAY, MAY 2, at the Central Institution of the City and Guilds of London Institute. A Previous Knowledge of the Differential Calculus will not be necessary. Fee for the Course, Ten Shillings. For Syllabus, apply at Central Institution, Exhibition Road, S.W.

PHILIP MAGNUS, Director and Secretary.

THE MASON SCIENCE COLLEGE, BIRMINGHAM.

PROFESSORSHIP OF PHYSIOLOGY.

The Council invite Applications, on or before June 30 next, for the above Appointment, the duties of which will commence on October 1, 1887.

Particulars of the Stipend and Conditions will be sent on application to the undersigned, to whom all Applications for the Appointment should be sent.

By a Resolution of the Council, Candidates are especially requested to abstain from canvassing.

GEO. H. MORLEY, Secretary.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL

HYDE PARK CORNER, S.W.

The SUMMER SESSION will commence on MONDAY, May 2.

The Fees for Perpetual Students are £125 on entrance, or £130 paid by instalments extending over three years.

£10 10s. will be deducted from these Fees in the case of Students who, under the conjoint scheme, do not require instruction in Chemistry and Materia Medica.

Second- and third-year Students are received upon payment of £90 and £65 respectively.

Dresserships, Clerkships, and all the House Appointments are awarded without extra Fees, and the latter on result of competition.

The William Brown £100 Exhibition, tenable for two years, and the £40 Exhibition, tenable for three years, are open to all Perpetual Students.

The following Entrance Scholarships are offered for competition in OCTOBER, and Students entering in the Summer Session are eligible to compete for them.

(1) A Scholarship, value £125, *for the Sons of Medical Men* who have entered the School during the current year.

(2) Two Scholarships, value £50 each, open to all Students commencing their Studies in May or October. *Subjects, Latin, French, or German, and Elementary Physics.*

(3) A Scholarship, value £90, open to all Students who have entered the School during the current year, having passed the Cambridge 1st M.B. since the previous October. *Subjects, Practical Chemistry and Elementary Biology, Physiology, and Anatomy.*

(4) A Scholarship, value £65, open to all Students who have entered the School during the current year having been previously signed up for, or passed the Oxford 1st M.B. or Cambridge 2nd M.B. *Subjects, Anatomy and Physiology.*

Other Prizes of the value of £150 are offered for competition Annually.

The Appointments of Obstetric Assistant, with a Salary of £100 a Year and Board and Lodging, Curator, £50, Medical and Surgical Registrars, £50 each, are awarded yearly upon the recommendation of the Medical School Committee.

The New Physiological Laboratories are now finished, and have been placed under the superintendence of Dr Delépine.

Prospectuses and fuller details may be obtained by application to

WILLIAM WADHAM, M.D., Dean.

LONDON HOSPITAL AND MEDICAL COLLEGE,

MILE-END, E.

The SUMMER SESSION will commence on MONDAY, May 2.

The New College Buildings are now complete, and afford more than double the former accommodation.

Intending Students are advised that, under the new regulations of the Examining Board in England, it is exceedingly advantageous to enter for the Summer Session. Students now entering are also eligible for the Entrance Scholarships in September.

The Hospital contains nearly 800 beds, and is the largest General Hospital in Great Britain.

General Fee for Lectures and Hospital Practice, 90 guineas in one sum, or 100 guineas in three instalments. The Resident and other Hospital Appointments are free to full Students.

Special entries may be made for Medical and Surgical Practice, also for the course of Practical Surgery.

The London Hospital is now in direct communication by rail and tram with all parts of the Metropolis, and the Metropolitan, Metropolitan District, South-Eastern, and East London Railways have stations within a minute's walk of the Hospital and College.

For Prospectus and particulars apply to

MUNRO SCOTT, Warden.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, S.E.

The SUMMER SESSION will commence on May 2. Students entering in the summer are eligible to compete for the Science Scholarships of 125 Guineas and £60, awarded in October.

There are numerous Prizes and Scholarships, and all Appointments are open to Students without extra charge.

Special Classes for the Examinations of the University of London are held throughout the year. A Register of Approved Lodgings and of Private Families receiving Students to reside is kept in the Secretary's Office.

Prospectus and all particulars can be obtained from the Medical Secretary Mr. G. RENDLE.

W. M. ORD, Dean.

EAST GRINSTEAD COLLEGIATE SCHOOL,

MAYPOLE ROAD, SUSSEX.

The object of the School is to afford a Sound Education, which will fit boys for either Professional or Commercial life. Most careful attention is paid to the requirements of boys intended for commercial pursuits. Boys are received from seven to fourteen years of age. There is a Junior Class, specially adapted to prepare the younger boys for the work of the higher classes. Each pupil will receive careful attention, especially in those subjects wherein he is weak. No injurious cramming encouraged. The course of Instruction includes all the subjects required at the various public examinations. The Principal has had many years' experience in good schools, and has proved himself a most successful Master. The Fees are moderate.—For Prospectus and particulars, apply to the PRINCIPAL.

AGRICULTURAL COLLEGIATE SCHOOL,

EAST GRINSTEAD, SUSSEX.

For Sons of Gentlemen, from seven years of age. The Course of Studies or Instruction is designed to prepare boys to occupy the positions of Landowners, Land Agents, Farmers, intending Colonists, &c. It provides full instruction in the practice and science of Agriculture and Estate Management, Management of Live Stock, Dairy Farming, Agricultural Chemistry, &c. Pupils are prepared for all the Examinations.

The College offers the following advantages:—A most superior education. A Staff of Masters selected for their qualifications as Scholars and their tried ability as Teachers. A Boarding Department carefully supervised and excellently appointed; its diet liberal, and all arrangements calculated to develop gentlemanly habits, and to produce feelings of self-respect.

The strictest attention to the moral and religious training of Pupils. Fees most moderate. References of high character to Parents of Pupils.

Prospectus and all particulars on application to the PRINCIPAL.

JUST PUBLISHED, Octavo, price 16s., cloth, bevelled boards,

PIONEERING IN NEW GUINEA.

By JAMES CHALMERS, of New Guinea,

Author of "Work and Adventure in New Guinea." With a Map, Two Portraits, and Illustrations, engraved by E. WHYMPER, from Photographs taken by Lindt, of Melbourne.

This volume contains an account of Mr. Chalmers' most important Explorations, including his long visit to the Cannibals of the Gulf, and also many sketches of New Guinea life, customs, habits, and beliefs. Mr. Chalmers has lived and travelled in New Guinea for the last eight years. He is known to all the tribes along the South-East Coast, and is the personal friend of many of the chiefs. He has successfully planted Christian teachers in many parts, and returns in a few weeks to carry on this work. He knows the New Guinea people in a way unapproached by any other white man, and as the power of Christianity is already beginning to influence their customs, this record of his travels and the condition in which he found the various tribes must always remain unique. The book contains much to interest those who are helping Christian missions, those who love true stories of thrilling adventure, and those who wish to know the habits and thoughts of a fine race of savages wholly untouched by Christianity or civilisation until 1872.

Mr. Chalmers, acting as interpreter, accompanied the Government Expeditions to proclaim the Protectorate which he describes in the book, and was with Sir Peter Scratchley until a few days before the death of the High Commissioner.

THE ENTOMOLOGIST'S MONTHLY MAGAZINE.

Price Sixpence, Monthly, 24 pages 8vo, with occasional Illustrations.
Conducted by C. G. Barrett, J. W. Douglas, W. W. Fowler, M.A., F.L.S., R. McLachlan, F.R.S., E. Saunders, F.L.S., and H. T. Stainton, F.R.S.

This Magazine, commenced in 1864, contains standard articles and notes on all subjects connected with Entomology, and especially on the Insects of the British Isles.

Subscription—Six Shillings per Volume, post free. The volumes commence with the June number in each year

Vols. I. to VI. (strongly bound in cloth) may be obtained by purchasers of the entire set to date, at the increased price of 10s each; the succeeding vols. may be had separately or together, at 7s. each.

London: GURNEY & JACKSON (Mr. Van Voorst's successors),
1, Paternoster Row.

N.B.—Communications, &c., should be sent to the Editors at the above address.

VAN HOUTEN'S
pure soluble **COCOA**
is the best and really the cheapest in the end.

The *British Medical Journal* says:—"'Van Houten's Cocoa' is admirable. In flavour it is perfect, and it is so pure, well prepared, and rich," &c., &c.

On the 1st of every Month.
JOURNAL OF BOTANY,
BRITISH AND FOREIGN.
Edited by James Britten, F.L.S., British Museum.

Contents:—Original Articles by leading Botanists.—Extracts, and Notices of Books and Memoirs.—Articles in Journals.—Botanical News.—Proceedings of Societies.

Price 1s 3d. Subscription for One Year, payable in advance, 12s.

London: WEST, NEWMAN, & CO., 54 Hatton Garden, E.C.

THE ZOOLOGIST:
A MONTHLY MAGAZINE OF NATURAL HISTORY.

Third Series. Edited by J. E. Harting, F.L.S., F.Z.S., Member of the British Ornithologists' Union; contains—

Original Articles by well-known naturalists in every branch of zoology; habits of animals; arrival and departure of migratory birds; occurrence of rare birds; distribution and migration of British fresh-water fish; new or rare marine fish; local aquaria; British reptiles; British land and fresh-water mollusca, with remarks on the haunts and habits of the species; and other matters of general interest to those who delight in natural history. Reports of the Linnean, Zoological, and Entomological Societies. Reviews of natural history books. Occasional translations from foreign zoological journals of important and interesting articles in various branches of zoology. There are occasional woodcuts.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

Now Ready, Fifth Edition, with 1178 Engravings, Crown 8vo, 15s

## A MANUAL OF BOTANY, including the

Structure, Classification, Properties, Uses, and Functions of Plants. By ROBERT BENTLEY, Professor of Botany in King's College, London, and to the Pharmaceutical Society.

London: J. & A. CHURCHILL, 11 New Burlington Street.

FOWNES-WATTS' CHEMISTRY.

PHYSICAL AND INORGANIC CHEMISTRY.

By HENRY WATTS, B.A., F.R.S., Author of "A Dictionary of Chemistry," &c. With Coloured Plate of Spectra and 150 Wood Engravings, Crown 8vo, 9s.

CHEMISTRY of CARBON COMPOUNDS;

or, ORGANIC CHEMISTRY. By HENRY WATTS, B.A., F.R.S. Edited by WILLIAM A. TILDEN, D.Sc., F.R.S., Professor of Chemistry in the Mason College, Birmingham. Second Edition. With Engravings, Crown 8vo, 10s.

*** These two volumes are based on the well-known Manual of the late Prof. Fownes, and form the Thirteenth Edition of that work

London: J. & A. CHURCHILL, 11 New Burlington Street.

Now Ready, 8vo, 6s

ELEMENTARY PRACTICAL BIOLOGY

—VEGETABLE. By THOMAS W. SHORE, M.D., B.Sc. (Lond.), Lecturer on Comparative Anatomy at St. Bartholomew's Hospital.

London: J. & A. CHURCHILL, 11 New Burlington Street.

On the 1st of every Month, price Sixpence.

THE ENTOMOLOGIST:

AN ILLUSTRATED JOURNAL OF BRITISH ENTOMOLOGY.

Edited by JOHN T. CARRINGTON

With the Assistance of

FREDERICK BOND, F.Z.S. | RICHARD SOUTH.
EDWARD A. FITCH, F.L.S. | J. JENNER WEIR, F.L.S.
F. BUCHANAN WHITE, M.D.

Contains Articles by well-known Entomologists on all Branches of the Science; on Insects injurious or beneficial to Farm or Garden; Notes on Habits, Life-Histories; occurrence of Rarities, &c.; there are Monthly Lists of Duplicates and Desiderata.

WOODCUT ILLUSTRATIONS and occasional LITHOGRAPHED and CHROMO-LITHOGRAPHED PLATES.

SIMPKIN, MARSHALL, & CO., Stationers' Hall Court.

Cheaper Issue, 8vo, Price 3s. 6d.

ESSEX FIELD CLUB SPECIAL MEMOIRS, VOL. I.

REPORT ON THE EAST ANGLIAN

EARTHQUAKE OF APRIL 22, 1884. By RAPHAEL MELDOLA, F.C.S., F.I.C., F.R.A.S., &c., Professor of Chemistry in the Finsbury Technical College, City and Guilds of London Institute, and WILLIAM WHITE, F.E.S., Member of the Geologists' Association. Drawn up by R. MELDOLA, and read in Abstract at the Meeting of the Essex Field Club, February 28, 1885. With Maps and other Illustrations. Cheaper Issue, 8vo, 3s 6d.

The *Athenæum* says:—"A distinctly valuable contribution to our knowledge of a subject of much obscurity, . . . The subject is one which only a few specialists will pursue within its narrower limits, but the curious facts collected, and the odd scraps of history referring to past earthquakes which have been gathered together are so numerous, so unexpected, and so well set, that the book will be found extremely interesting to the general reader, as well as a suggestive and severe study for the man of science."

MACMILLAN & CO., LONDON

Now Ready, Part XXXVII., Demy 8vo, Price 3s. 6d.

BRAIN:

A JOURNAL OF NEUROLOGY.

EDITED FOR THE NEUROLOGICAL SOCIETY OF LONDON, BY A. DE WATTEVILLE.

Contents.

ORIGINAL ARTICLE—
"The Muscular Sense"; its Nature and Cortical Localisation. By H. Charlton Bastian, M.D., F.R.S.
Discussion on Dr. Charlton Bastian's Paper by—
Dr. Ferrier.
Mr. Sully.
Dr. Ross.
Sir James Crichton-Browne.
Dr. Hughlings-Jackson.
Prof. Horsley.
Prof. Haycraft.
Dr. Mercier.
Dr. de Watteville.
Reply of Dr. Charlton Bastian.

CRITICAL DIGEST—
Some Recent Observations on Peripheral Neuritis. By R. H. Pierson, M.D. (Pirna, Dresden)

ABSTRACTS OF BRITISH AND FOREIGN JOURNALS—
Landouzy and Déjérine on Progressive Atrophic Myopathy involving the Face. By A. T. Myers, M.D.

MACMILLAN & CO., LONDON.

DER NATURFORSCHER,

Wochenblatt zur Verbreitung der Fortschritte in den Naturwissenschaften, XIX. Jahrgang.

Gegründet von Dr. W. Sklarek, u. herausgegeben von Dr. O. SCHUMANN, Privatdocent an der Universität Tübingen.

Price for 52 Numbers, 16s. per annum, or 18s. 6d. post free

Tubingen: LAUPP.

London and Edinburgh: WILLIAMS & NORGATE.

HOW & CO.'S

Geological Transparencies for the Lantern

Descriptive Catalogue on Application.

WALKER'S SPECIFIC GRAVITY BALANCE [illegible] ROCKS AND MINERALS.

HOW & CO.'S POCKET MICROSCOPE [illegible]

MICRO-PETROLOGY.—Sections of Pitchstones, [illegible] Granites, Syenites, Diorites, Gabbros, Dolerites, Basalts, Ta[illegible] Trachytes, Andesites, Porphyrites, Rhyolites, Lavas, Ashes, Gn[illegible] Schists, Limestones, &c., price 1s. 6d. each.

JAMES HOW & CO., 73 FARRINGDON STREET, LONDON.

THE "HANSA,"

Published since 1864 in Hamburg, is the only independent professional paper in Germany dedicated exclusively to Maritime Objects. Essays, Critiques, Reviews, Reports, Advertisements. Strict eye kept upon the development of Maritime Affairs in every respect. Every second Sunday one Number in 4to at least; frequent supplements and drawings. Subscription at any time; preceding numbers of the year furnished subsequently. Price 1[illegible] for twelve months. Advertisements 4d. a line widely spread by this paper; considerable abatement for 3, 6, 12 months' insertion. Business Office: Aug. Meyer and Dieckmann, Hamburg, Alterwall, 28. Edited by W. von [illegible] M.R. Hamburg, Alexander Street 8.

SCIENTIFIC WORTHIES.

The following is a list of the Portraits that have appeared in the above Series.

MICHAEL FARADAY.
THOMAS HENRY HUXLEY.
CHARLES DARWIN.
JOHN TYNDALL.
GEORGE GABRIEL STOKES.
SIR CHARLES LYELL.
SIR CHARLES WHEATSTONE.
SIR WYVILLE THOMSON.
ROBERT WILHELM BUNSEN.
ADOLF ERIK NORDENSKJÖLD.
SIR WILLIAM THOMSON.
HERMANN L. F. HELMHOLTZ.
SIR JOSEPH DALTON HOOKER.
WILLIAM HARVEY.
SIR GEORGE B. AIRY.
J. LOUIS R. AGASSIZ.
JEAN BAPTISTE ANDRÉ DUMAS.
SIR RICHARD OWEN.
JAMES CLERK MAXWELL.
JAMES PRESCOTT JOULE.
WILLIAM SPOTTISWOODE.
ARTHUR CAYLEY.
SIR C. W. SIEMENS.
JOHN COUCH ADAMS.

Proof impressions of these, printed on India paper, may be had from the Publishers, price 5s. each, or the Set of 24 Portraits in a Handsome Portfolio for £6 5s. 0d., carriage paid.

THE PORTFOLIO MAY BE HAD SEPARATELY, PRICE 6s.

Cheques and Money Orders payable to MACMILLAN & CO.,

OFFICE [illegible] "NATURE," 29, BEDFORD STREET, STRAND.

MESSRS. MACMILLAN & CO.'S SCIENTIFIC WORKS.

NATURAL PHILOSOPHY.

A Text-Book of the Principles of Physics. By ALFRED DANIELL, M.A., LL.B., D.Sc., F.R.S.E., late Lecturer on Physics in the School of Medicine, Edinburgh. With Illustrations. Second Edition. Revised and Enlarged. Medium 8vo. 21s.

Elementary Practical Physics, Lessons in. By Professor BALFOUR STEWART, F.R.S., and W. W. HALDANE GEE, B.Sc. Crown 8vo.
Part I.—GENERAL PHYSICAL PROCESSES. 6s.
Part II.—ELECTRICITY AND MAGNETISM. 7s. 6d.
Part III.—OPTICS, HEAT, AND SOUND. [In preparation.

A School Course of Practical Physics. By the same Authors.
Part. I.—ELECTRICITY AND MAGNETISM. [In the press.

Physics, Elementary Lessons in. By Professor BALFOUR STEWART, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d. (Questions on, 2s.)

Primer of Physics. By the same Author. With numerous Illustrations. New Edition, with Questions. 18mo. 1s. [Science Primers.

On Light. Being the Burnett Lectures, delivered in Aberdeen in 1883-1885. By GEORGE GABRIEL STOKES, M.A., P.R.S., &c., Fellow of Pembroke College, and Lucasian Professor of Mathematics in the University of Cambridge. First Course. ON THE NATURE OF LIGHT.—Second Course. ON LIGHT AS A MEANS OF INVESTIGATION. Crown 8vo. 2s. 6d. each.
THIRD COURSE. ON THE BENEFICIAL EFFECTS OF LIGHT. [In the press.

Spectrum Analysis. Lectures delivered in 1868 before the Society of Apothecaries of London. By Sir HENRY E. ROSCOE, LL.D., F.R.S., Professor of Chemistry in the Owens College, Victoria University, Manchester. Fourth Edition, revised and considerably enlarged by the Author and by ARTHUR SCHUSTER, F.R.S., Ph.D., Professor of Applied Mathematics in the Owens College, Victoria University. With Appendices, numerous Illustrations, and Plates. Medium 8vo. 21s.

Mechanical Theory of Heat. By R. Clausius. Translated by WALTER R. BROWNE, M.A. late Fellow of Trinity College, Cambridge. Crown 8vo. 10s. 6d.

Heat. By P. G. Tait, M.A., Sec. R.S.E., formerly Fellow of St. Peter's College, Cambridge Professor of Natural Philosophy [illegible] University of Edinburgh. Crown 8vo. 6s.

Light: [illegible]ourse of Experimental Optics, CHIEFLY [illegible]TH THE LANTERN. By LEWIS WRIGHT. With 200 Engravings and Coloured Plates. Crown 8vo. 7s 6d.

Natural Philosophy for Beginners. By I. TODHUNTER, M.A., F.R.S. Fcap. 8vo. Part I.—The Properties of Solid and Fluid Bodies. With Illustrations. 3s. 6d. Part II.—Sound, Light, and Heat. 3s. 6d.

Electrostatics and Magnetism, Reprints of Papers on. By Sir WILLIAM THOMSON, D.C.L., LL.D., F.R.S., F.R.S.E., Fellow of St. Peter's College, Cambridge and Professor of Natural Philosophy in the University of Glasgow. Second Edition. Medium 8vo. 18s.

Electricity and Magnetism. By Professor SILVANUS THOMPSON. With numerous Illustrations. Fcap. 8vo. [illegible]

Electricity and Magnetism, Absolute Measurements in. By Professor ANDREW GRAY, M.A., F.R.S.E. Pott 8vo. 3s. 6d.

Electric Light Arithmetic. By R. E. Day, M.A. Pott 8vo. 2s.

Heat and Electricity, A Collection of Examples on. By H. H. TURNER, B.A., Fellow of Trinity College, Cambridge. Crown 8vo. 2s. 6d.

Steam, An Elementary Treatise on. By J. PERRY, C.E., Professor of Engineering in the Imperial College of Engineering, Yedo. With Illustrations, Numerical Examples, and Exercises. Fcap. 8vo. 4s 6d.

Sound, Elementary Lessons on. By Dr. W. H. STONE. With Illustrations. Fcap. 8vo. 3s. 6d.

Units and Physical Constants. By J. D. EVERETT, M.A., D.C.L., F.R.S., F.R.S.E., Professor of Natural Philosophy, Queen's College, Belfast. Second Edition. Globe 8vo. 5s.

Applied Mechanics: An Elementary General Introduction to the Theory of Structures and Machines. By JAMES H. COTTERILL, F.R.S., Associate Member of the Council of the Institution of Naval Architects, Associate Member of the Institution of Civil Engineers, Professor of Applied Mechanics in the Royal Naval College, Greenwich. Medium 8vo. 18s.

NATURAL PHILOSOPHY—*Continued.*

The Kinematics of Machinery. Outlines of a Theory of Machines. By Professor F. REULEAUX. Translated and Edited by Professor A. B. W. KENNEDY, C.E. With 450 Illustrations. Medium 8vo. 21s.

The Mechanics of Machinery. By A. B. W. KENNEDY, M.Inst.C.E., Professor of Engineering and Mechanical Technology in University College, London. With numerous Illustrations. Crown 8vo. 12s. 6d.

Elementary Science, Numerical Tables and CONSTANTS IN. By SYDNEY LUPTON, M.A., F.C.S., F.C.I. Globe 8vo. 2s. 6d.

Chemical Arithmetic. With 1200 Examples. By the same Author. Second Edition. Globe 8vo. 4s. 6d.

ASTRONOMY.

Popular Astronomy. By S. Newcomb, LL.D., Professor U.S. Naval Observatory. With 112 Illustrations and 5 Maps of the Stars. Second Edition, revised. 8vo. 18s.

Popular Astronomy. By Sir G. B. Airy, K.C.B., F.R.S., late Astronomer-Royal. With numerous Illustrations. Fcap. 8vo. 4s. 6d.

Astronomy, Elementary Lessons in. By J. NORMAN LOCKYER, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 5s. 6d. (Questions on, 1s. 6d.)

The Chemistry of the Sun. By J. Norman LOCKYER, F.R.S. With Illustrations. Demy 8vo. 14s.

Primer of Astronomy. By J. Norman LOCKYER, F.R.S. With numerous Illustrations. New Edition. 18mo. 1s. [Science Primers.

CHEMISTRY.

Inorganic and Organic Chemistry. A Complete Treatise on Inorganic and Organic Chemistry. By Sir HENRY E. ROSCOE, F.R.S., and Professor C. SCHORLEMMER, F.R.S. With numerous Illustrations. Medium 8vo.
Vols. I. and II.—INORGANIC CHEMISTRY.
Vol. I.—The Non-Metallic Elements. 21s. Vol. II. Part I.—Metals 18s. Vol. II. Part II.—Metals. 18s.
Vol. III.—ORGANIC CHEMISTRY. Three Parts.
The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. With numerous Illustrations. Medium 8vo. Parts I. and II., 21s. each. Part III., 18s.

Elements of Chemical Physics. By Josiah P. COOKE, Junr., Erving Professor of Chemistry and Mineralogy in Harvard University. Fourth Edition. Royal 8vo. 21s.

A Manual of the Chemistry of the Carbon COMPOUNDS, OR ORGANIC CHEMISTRY. By C. SCHORLEMMER, F.R.S., Professor of Chemistry in the Victoria University, the Owens College, Manchester. With Illustrations. 8vo. 14s.

The Elements of Thermal Chemistry. By M. M. PATTISON MUIR, M.A., F.R.S.E., Fellow and Prælector of Chemistry in Gonville and Caius College, Cambridge; Assisted by DAVID MUIR WILSON. 8vo. 12s. 6d.

The Study of Chemistry, an Introduction TO. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

Compounds of Carbon; or, Organic Chemistry, an Introduction to the Study of. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Crown 8vo. 6s. 6d.

Chemistry, Elementary Lessons in. By Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 4s. 6d. Problems adapted to the same, by Professor THORPE. With Key. 18mo. 2s.

Owens College Junior Course of Practical CHEMISTRY. By F. JONES. With Preface by Sir HENRY E. ROSCOE, F.R.S. New Edition. With numerous Illustrations. Fcap. 8vo. 2s. 6d.

Questions on Chemistry. A Series of Problems and Exercises in Inorganic and Organic Chemistry. By F. JONES, F.R.S.E., F.C.S. Fcap. 8vo. 3s.

Primer of Chemistry. By Sir Henry E. ROSCOE, F.R.S. With numerous Illustrations. New Edition. With Questions. 18mo. 1s. [Science Primers.

Chemical Theory, Experimental Proofs of, FOR BEGINNERS. By WILLIAM RAMSAY, Ph.D. Fcap. 8vo. 2s. 6d.

MACMILLAN & CO., LONDON.

Printed by RICHARD CLAY AND SONS, at 7 and 8 Bread Street Hill, Queen Victoria Street, in the City of London, and Published by MACMILLAN AND CO., at the Office, 29 and 30 Bedford Street, Covent Garden.—THURSDAY, April 28, 1887.
